	18.7	Inexpensive Stocks with Low52WkPerc < Q1(Low52WkPerc)	325
		18.7.1 Summary Statistics of Return on Equity (ROE)	326

	18.7.2	Stocks with ROE $> Q3(ROE)$	327
	18.7.3	Summary Statistics of Return on Equity (ROA)	328
	18.7.4	Stocks with ROA $> Q3(ROA)$	329
	18.7.5	ROE versus ROA and colored by Price rel. to 52 Week Low	330
	18.7.6	Summary Statistics of All key variables in REIT Services	331
18.8	ANAL	YSIS OF INDUSTRY REIT	333
	18.8.1	PROFITABILITY OF INDUSTRY REIT	335

# Overview of this Book

Dec 30, 2023 V1.3

Delve into the world of Exploratory Data Analysis (EDA) - an imperative approach to data analysis that focuses on discovering and summarizing the main features of datasets primarily via statistical graphics and visualization techniques. EDA facilitates a comprehensive understanding of the data prior to initiating formal modeling or hypothesis testing.

In this comprehensive guide, we illuminate the applications and nuances of utilizing the R programming language for effective Exploratory Data Analysis.

Live Case: To highlight the practical usage of the concepts discussed, this book features a live project that employs R for conducting EDA on a real-world dataset. The dataset pertains to the S&P500 stocks, a choice that adds real-world relevance to the techniques and methodologies illustrated. Throughout the book, you will find multiple sample codes that navigate through this data, probing into financial metrics like Return on Equity, Return on Assets, and Return on Invested Capital of S&P500 shares.

# Introduction to Exploratory Data Analysis (EDA)

The journey of EDA can be visualized as a sequence of interrelated steps:

**Data Cleaning:** The journey begins with the purification of data through processes such as handling missing data, eliminating outliers, and other data cleansing procedures.

Univariate Analysis: In this phase, individual fields in the dataset are analyzed to better grasp their distribution, outliers, and unique values. It typically involves statistical plots measuring central tendencies like mean, median, mode, frequency distribution, quartiles, and so forth.

Bivariate Analysis: This stage is characterized by the exploration of two variables to establish their empirical relationship. Techniques include the usage of scatter plots for continuous variables or crosstabs for categorical data.

Multivariate Analysis: This advanced step delves into the analysis involving more than two variables, helping to unearth the interactions between different fields in the dataset.

**Data Visualization:** Here, the creation of plots like histograms, box plots, scatter plots, etc., comes into play. These visual tools are used to identify patterns, relationships, or outliers within the dataset.

**Insight Generation:** The final stage encompasses the generation of insights post visualizations and statistical tests. These insights pave the way for further queries, hypotheses, and model building.

The EDA process is an integral precursor to more advanced analyses. It equips us with the ability to validate or refute initial hypotheses, enabling us to craft more precise questions or hypotheses that can guide further statistical analysis and testing.

### Overview of the Book Chapters

#### **Chapter 01: Exploring R Programming**

Chapter 01 acts as your compass, guiding you through the R programming language's multifaceted applications in statistical computations and data analysis. It unravels the basics of R, including its history, usage, and platforms. It guides the reader through the R and RStudio installation processes, while also shedding light on alternatives like Jupyter Notebook and Visual Studio Code. The chapter then dives deeper into the practical aspects of using R, elucidating mathematical and statistical operations through real-world examples.

#### Chapter 02: Exploring R Packages

Chapter 02 transports you into the expansive world of R packages, illuminating their significance, sources, and practical applications. It elucidates the process of installing an R package and showcases notable examples such as ggplot2 for creating visualizations. It also provides solutions for addressing challenges users might encounter when using R packages.

#### **Chapter 03: Exploring Data Structures**

Chapter 03 immerses you into the core data structures of R, primarily focusing on vectors. This chapter guides you through creating and operating on vectors - numeric, character, and logical - highlighting their significance in computations and data management. It demonstrates the application of various mathematical, logical, and statistical operations on vectors. The chapter also provides insights into string manipulation within vectors and the key role of vectors in data analysis and modeling.

#### Chapter 04: Reading Data into R

Chapter 04 advances our understanding of data frames in R, highlighting techniques to read different file formats into a data frame, manage the working directory, merge data frames, and introduces tibbles. It explains the workings of a 'working directory' and showcases how to navigate and alter it for efficient file handling. The chapter illustrates how to read various file formats, such as CSV and Excel, into a data frame and merge multiple data sources. Importantly, it intorduces tibbles, a modern take on data frames, discussing their creation, conversion, and distinct features.

#### **Chapter 05: Exploring Dataframes**

Chapter 05 embarks on a thorough journey into data manipulation in R, offering insights into key tools like 'dplyr', logical operations, statistical functions, and the creation of custom functions. It introduces pivotal 'dplyr' verbs and the pipe operator for data manipulation, explores logical operations for data subsetting, and presents essential statistical functions to extract valuable insights from data. It delves into the 'summary()' function for providing basic descriptive statistics and illustrates the creation and utility of custom functions in R. This chapter empowers the reader to effectively manage, manipulate, and extend the functionalities of R for comprehensive data analysis.

### Chapter 06: Exploring tibbles & dplyr

Chapter 06 thoroughly discusses the tibble data structure and the dplyr package in R. It begins by introducing tibbles, an enhanced version of data frames, known for their user-friendly printing, reliable subsetting, and flexible data type handling. The chapter then shifts to the powerful dplyr package, which offers a cohesive set of functions for efficient data manipulation in R. Key concepts, such as the various dplyr "verbs" and the pipe operator, are illustrated with examples using the mtcars dataset. By touching upon additional dplyr functions like rename(), group\_by(), and slice(), this chapter builds a profound understanding of data manipulation and management in R using tibbles and dplyr.

### Chapter 07: Categorical Data - Exploring Univariate Categorical Data

Chapter 07 explores how to summarize and visualize univariate, categorical data. It introduces the basic concept behind categorical data, with a deep dive into its two primary types: nominal and ordinal. It explains nominal data as variables with categories without any inherent order, while ordinal data possess categories with specific rankings. The chapter then extensively discusses factor variables in R, a key tool for handling categorical data, with illustrative examples from the mtcars dataset. It further delves into the analysis and visualization of categorical

data, discussing the creation of frequency tables, computation of proportions and percentages, and the use of ggplot2 for bar plots. Lastly, it introduces the ggpie() function from the ggpubr package for creating pie charts within the ggplot2 framework.

# Chapter 08: Categorical x Categorical data (1 of 2) - Exploring Bivariate Categorical Data

Chapter 08 explores how to summarize and visualize bivariate, categorical data. It expands upon the exploration of categorical data, focusing specifically on visualizing bivariate categorical data using R. The chapter covers grouped bar plots, stacked bar plots, and mosaic plots, distinguishing between the various methods and offering detailed coding examples. Both base R functions and the ggplot2 library are utilized for these visualizations, with ggplot2 providing superior customization capabilities. The chapter introduces mosaic plots, using the base R mosaicplot() function and the mosaic() function in the vcd package for demonstrations. Further, it discusses the ggmosaic package, rounding off a comprehensive exploration of visualization techniques for bivariate categorical data.

# Chapter 09: Categorical x Categorical data (2 of 2) - Exploring Multivariate Categorical Data

Chapter 09 explores how to summarize and visualize multivariate, categorical data. It explores multivariate categorical variables and the complex relationships and dependencies they exhibit. The chapter leverages R to construct three-dimensional contingency tables and segment these tables by various variables for unique data perspectives. The chapter elaborates on visualizing this data through three-dimensional bar plots and mosaic plots, which aid in interpreting the frequency of combinations of multiple variables. The chapter also explores four-way relationships between categorical variables, utilizing four-dimensional contingency tables and mosaic plots. As a result, the chapter imparts a robust understanding of handling and visualizing multivariate categorical data, preparing readers to effectively navigate and analyze complex datasets. Together with its predecessors, this chapter completes a comprehensive overview of handling and visualizing multivariate categorical data.

#### Chapter 10: Continuous Data (1 of 2) - Exploring Univariate Continuous Data

Chapter 10 explores how to summarize and visualize univariate, continuous data. It demonstrates how to calculate central tendency and variability measures with R's inbuilt functions. The chapter also employs R's 'summary()' and the psych package's 'describe()' functions for a comprehensive data overview. The utilization of various visualization techniques like bee swarm plots, box plots, violin plots, histograms, density plots, and cumulative distribution function (CDF) plots are presented to aid in understanding data patterns and distributions.

# Chapter 11: Continuous Data (2 of 2) - Exploring Univariate Continuous Data, using ggplot2

Chapter 11 demonstrates the use of the popular **ggplot2** and **ggpubr** packages to further explore *univariate*, *continuous* data. We showcase techniques like histograms, density plots, box plots, bee swarm plots, and violin plots. Special attention is given to customizing these visuals. We also introduce the **ggarrange()** function for combining multiple plots.

#### Chapter 12: Categorical x Continuous data (1 of 2)- Exploring bivariate data

Chapter 12 delves into the relationship between **Categorical** and **Continuous** data, emphasizing how to summarize and illustrate continuous data across categories. We highlight methods for statistical analysis and data manipulation techniques, like grouping and filtering based on categorical variables. Tools like box plots, histograms, and density plots are used to showcase data distributions. We showcase data manipulation, using functions like aggregate() to understand relationships. Our exploration includes diverse visualizations, like the Bee Swarm plot, histograms, and mean plots, all underpinned by R's robust capabilities. This chapter offers a holistic view of handling and visualizing intertwined categorical and continuous data.

# Chapter 13: Categorical x Continuous data (1 of 2)- Exploring bivariate data, using ggplot2

Chapter 13 demonstrates the use of the popular ggplot2 and dplyr packages to further explore bivariate continuous data across categories. Visualization with ggplot2 and ggpubr offers sophisticated histograms, faceted plots, boxplots, and embedded violin plots. Our approach leverages R for deep insights into data interactions.

# Chapter 14: Continuous x Continuous data (1 of 2)- Exploring bivariate continuous data

Chapter 14 explores the process of summarizing and visualizing the relationship between bivariate continuous data. Focusing on scatter plots, we demonstrate how to create them, and ways to customize their appearance for enhanced clarity and presentation. For example, scatter plots can reveal trends, clusters, outliers, and more. The chapter also emphasizes on color coding based on categorical data and introducing regression lines for a better understanding of the data trends. Furthermore, we dive into scatter plot matrices or SPLOMs, which provide a comprehensive visualization of relationships among multiple variables simultaneously.

# Chapter 15: Continuous x Continuous data (2 of 2)- Exploring bivariate continuous data, using ggplot2

Chapter 15 explores bivariate continuous data using the ggplot2 package. In particular, we demonstrate scatterplots and scatterplot matrices, as effective tools to analyze pairwise relationships among multiple variables. Scatterplot matrices help us identify correlations, patterns, and potential outliers. We further illustrate the enhancement of scatter plots by integrating categorical variables, using color distinctions or faceting. Throughout, ggplot2 proves vital in making these visual explorations straightforward and insightful.

#### Live Case Study - Exploring S&P500 Data (1 of 2)

This study offers a practical exploration of the S&P500, a prominent stock market index of 500 major U.S. publicly traded companies. The chapter involves a deep-dive into a real-world dataset of S&P500 stocks, highlighting the structure and content of the dataset through the lens of R functions and packages. This includes careful data management and data quality steps such as renaming columns, removing rows with null or blank values, and transforming specific columns into factor variables. Through practical examples and code, this chapter provides a comprehensive foundation for further analysis of the S&P500 dataset.

We analyze the technical rating (e.g., Buy, Sell) and compute the share prices in relation to their 52-week lows. We also analyze the distribution of S&P500 shares across different sectors, visualize the data. Market capitalization is another focal point: we break down the market cap by sectors, offer summary statistics. Lastly, we compute price statistics relative to each stock's 52-week low across various sectors.

### Live Case Study - Exploring S&P500 Data (2 of 2)

This part of the Case Study conducts a comprehensive review of the Health Technology segment within the S&P 500. Narrowing our focus to the REIT Industry within the Finance Sector, we zeroed in on 29 notable stocks. We tWe analyze which one is the best investment opportunity.

# 1 01: Exploring R programming

Dec 30, 2023.

# 1.1 Overview of R programming

- 1. R is an **open-source** software environment and programming language designed for statistical computing, data analysis, and visualization. It was developed by Ross Ihaka and Robert Gentleman at the University of Auckland in New Zealand during the early 1990s.
- 2. R offers a wide range of statistical techniques, including linear and nonlinear modeling, classical statistical tests, and support for data manipulation, data import/export, and compatibility with various data formats.
- 3. R offers **free usage**, **distribution**, **and modification**, making it accessible to individuals with various budgets and resources who wish to learn and utilize it.
- 4. The Comprehensive R Archive Network (CRAN) serves as a valuable resource for the R programming language. It offers a vast collection of downloadable packages that expand the functionality of R, including tools for machine learning, data mining, and visualization.
- 5. R stands out as a prominent tool within the data analysis community, attracting a large and active user base. This community plays a vital role in the ongoing maintenance and development of R packages, ensuring a thriving ecosystem for continuous improvement.
- 6. One of R's strengths lies in its **powerful and flexible graphics system**, empowering users to create visually appealing and informative data visualizations for data exploration, analysis, and effective communication.
- 7. R facilitates the creation of **shareable and reproducible scripts**, promoting transparency and enabling seamless collaboration on data analysis projects. This feature enhances the ability to replicate and validate results, fostering trust and credibility in the analysis process.

8. R exhibits strong **compatibility with other programming languages** like Python and SQL, as well as with popular data storage and manipulation tools such as Hadoop and Spark. This compatibility allows for smooth integration and interoperability, enabling users to leverage the strengths of multiple tools and technologies for their datacentric tasks. [1]

### 1.2 Running R locally

R could be run locally or in the Cloud. We discuss running R locally. We discuss running it in the Cloud in the next sub-section.

#### 1.2.1 Installing R locally

Before running R locally, we need to first install R locally. Here are general instructions to install R locally on your computer:\

- 1. Visit the official website of the R project at https://www.r-project.org/.
- 2. On the download page, select the appropriate version of R based on your operating system (Windows, Mac, or Linux).
- 3. After choosing your operating system, click on a mirror link to download R from a reliable source.
- 4. Once the download is finished, locate the downloaded file and double-click on it to initiate the installation process. Follow the provided instructions to complete the installation of R on your computer. [2]

### 1.2.2 Running R locally in an Integrated Development Environment (IDE)

An Integrated Development Environment (IDE) is a software application designed to assist in software development by providing a wide range of tools and features. These tools typically include a text editor, a compiler or interpreter, debugging tools, and various utilities that aid developers in writing, testing, and debugging their code.

When working with the R programming language on your local machine and looking to take advantage of IDE features, you have several options available:

1. **RStudio:** RStudio is a highly popular open-source IDE specifically tailored for R programming. It boasts a user-friendly interface, a code editor with features like syntax highlighting and code completion, as well as powerful debugging capabilities. RStudio also integrates seamlessly with version control systems and package management tools, making it an all-inclusive IDE for R development.

- 2. Visual Studio Code (VS Code): While primarily recognized as a versatile code editor, VS Code also offers excellent support for R programming through extensions. By installing the "R" extension from the Visual Studio Code marketplace, you can enhance your experience with R-specific functionality, such as syntax highlighting, code formatting, and debugging support.
- 3. **Jupyter Notebook:** Jupyter Notebook is an open-source web-based environment that supports multiple programming languages, including R. It provides an interactive interface where you can write and execute R code within individual cells. Jupyter Notebook is widely employed for data analysis and exploration tasks due to its ability to blend code, visualizations, and text explanations seamlessly.

These IDE options vary in their features and user interfaces, allowing you to choose the one that aligns best with your specific needs and preferences. It's important to note that while R can also be run through the command line or the built-in R console, utilizing an IDE can significantly boost your productivity and enhance your overall development experience. [3]

#### 1.2.3 RStudio

RStudio is a highly popular integrated development environment (IDE) designed specifically for R programming. It offers a user-friendly interface and a comprehensive set of tools for data analysis, visualization, and modeling using R.

Some notable features of RStudio include:

- 1. **Code editor**: RStudio includes a code editor with advanced features such as syntax highlighting, code completion, and other functionalities that simplify the process of writing R code.
- 2. **Data viewer**: RStudio provides a convenient data viewer that allows users to examine and explore their data in a tabular format, facilitating data analysis.
- 3. **Plots pane**: The plots pane in RStudio displays graphical outputs generated by R code, making it easy for users to visualize their data and analyze results.
- 4. Console pane: RStudio includes a console pane that shows R code and its corresponding output. It enables users to execute R commands interactively, enhancing the coding experience.
- 5. **Package management:** RStudio offers tools for managing R packages, including installation, updating, and removal of packages. This simplifies the process of working with external libraries and extending the functionality of R.
- 6. **Version control**: RStudio seamlessly integrates with version control systems like Git, empowering users to efficiently manage and collaborate on their code projects.

7. Shiny applications: RStudio allows users to create interactive web applications using Shiny, a web development utility for R. This feature enables the creation of dynamic and user-friendly interfaces for R-based applications. [4]

To run RStudio on your computer, you can follow these simple steps:

- 1. **Download RStudio**: Visit the RStudio download page and choose the version of RStudio that matches your operating system.
- 2. **Install RStudio**: Once the RStudio installer is downloaded, run it and follow the instructions provided to complete the installation process on your computer.
- 3. **Open RStudio:** After the installation is finished, you can open RStudio by double-clicking the RStudio icon on your desktop or in the Applications folder.
- 4. **Start an R session**: In RStudio, click on the Console tab to initiate an R session. You can then enter R commands in the console and execute them by clicking the "Run" button or using the shortcut Ctrl+Enter (Windows) or Cmd+Enter (Mac). [5]

# 1.3 Running R in the Cloud

Running R in the cloud allows users to access R and RStudio from anywhere with an internet connection, eliminating the need to install R locally. Several cloud service providers, such as Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Platform (GCP), offer virtual machines (VMs) with pre-installed R and RStudio.

Here are some key advantages and disadvantages of running R in the cloud:

#### **Benefits:**

- 1. **Scalability**: Cloud providers offer scalable computing resources that can be adjusted to meet specific workload requirements. This is particularly useful for data-intensive tasks that require significant computational power.
- 2. Accessibility and Collaboration: Cloud-based R allows users to access R and RStudio from any location with an internet connection, facilitating collaboration on projects and data sharing.
- 3. Cost-effectiveness: Cloud providers offer flexible pricing models that can be more cost-effective than running R on local hardware, especially for short-term or infrequent use cases.
- 4. **Security**: Cloud service providers implement various security features, such as firewalls and encryption, to protect data and applications from unauthorized access or attacks. [6]

#### Drawbacks:

- 1. **Internet Dependency**: Running R in the cloud relies on a stable internet connection, which may not be available at all times or in all locations. This can limit the ability to work on data analysis and modeling projects.
- 2. **Learning Curve**: Utilizing cloud computing platforms and tools requires familiarity, which can pose a learning curve for users new to cloud computing.
- 3. **Data Privacy**: Storing data in the cloud may raise concerns about data privacy, particularly for sensitive or confidential information. While cloud service providers offer security features, users must understand the risks and take appropriate measures to secure their data.
- 4. Cost Considerations: While cloud computing can be cost-effective in certain scenarios, it can also become expensive for long-term or high-volume use cases, especially if additional resources like data storage are required alongside computational capacity. [6]

#### 1.3.1 Cloud Service Providers - Posit, AWS, Azure, GCP

Here is a comparison of four prominent cloud service providers: Posit, AWS, Azure, and GCP.

#### Posit:

- Posit is a relatively new cloud service provider that focuses on offering high-performance computing resources specifically for data-intensive applications.
- They provide bare-metal instances that ensure superior performance and flexibility.
- Posit is dedicated to data security and compliance, prioritizing the protection of user data.
- They offer customizable hardware configurations tailored to meet specific application requirements.

#### AWS:

- AWS is a well-established cloud service provider that offers a wide range of cloud computing services, including computing, storage, and database services.
- It boasts a large and active user community, providing abundant resources and support for users.
- AWS provides flexible pricing options, including pay-as-you-go and reserved instance pricing.

• They offer a comprehensive set of tools and services for managing and securing cloud-based applications.

#### Azure:

- Azure is another leading cloud service provider that offers various cloud computing services, including computing, storage, and networking.
- It tightly integrates with Microsoft's enterprise software and services, making it an attractive option for organizations using Microsoft technologies.
- Azure provides flexible pricing models, including pay-as-you-go, reserved instance, and spot instance pricing.
- They offer a wide array of tools and services for managing and securing cloud-based applications.

#### GCP:

- GCP is a cloud service provider that provides a comprehensive suite of cloud computing services, including computing, storage, and networking.
- It offers specialized tools and services for machine learning and artificial intelligence applications.
- GCP provides flexible pricing options, including pay-as-you-go and sustained use pricing.
- They offer a range of tools and services for managing and securing cloud-based applications. [7]

# 1.4 Getting Started with R - Inbuilt R functions

#### 1.4.1 Mathematical Operations

R is a powerful programming language for performing mathematical operations and statistical calculations. Here are some common mathematical operations in R.

1. **Arithmetic Operations**: We can perform basic arithmetic operations such as addition (+), subtraction (-), multiplication (\*), and division (/).

```
# Addition and Subtraction
5+9-3
```

#### [1] 11

```
# Multiplication and Division (5 + 3) * 7 / 2 (5+3)*7/2
```

#### [1] 28

2. **Exponentiation and Logarithms**: We can raise a number to a power using the ^ or \*\* operator or take logarithms.

```
# Exponentiation
2^6
```

#### [1] 64

```
# Exponential of x=2 i.e. e^2
exp(2)
```

#### [1] 7.389056

```
# logarithms base 2 and base 10 log2(64) + log10(100)
```

#### [1] 8

- 3. Other mathematical functions: R has many additional useful mathematical functions
- We can find the absolute value, square roots, remainder on division.

```
# absolute value of x=-9
abs(-9)
```

#### [1] 9

```
# square root of x=70
sqrt(70)
```

#### [1] 8.3666

```
# remainder of the division of 11/3 11 \% 3
```

#### [1] 2

• We can round numbers, find their floor, ceiling or up to a number of significant digits

```
# Value of pi to 10 decimal places
pi = 3.1415926536

# round(): This function rounds a number to the given number of decimal places
# For example, round(pi, 3) returns 3.142
round(pi, 3)
```

#### [1] 3.142

```
# ceiling(): This function rounds a number up to the nearest integer.
# For example, ceiling(pi) returns 4
ceiling(pi)
```

#### [1] 4

```
# floor(): This function rounds a number down to the nearest integer.
# For example, floor(pi) returns 3.
floor(pi)
```

#### [1] 3

```
# signif(): This function rounds a number to a specified number of significant digits.
# For example, signif(pi, 3) returns 3.14.
signif(pi, 3)
```

#### [1] 3.14

4. Statistical calculations: R has many built-in functions for statistical calculations, such as mean, median, standard deviation, and correlation.

```
# Create a vector of 7 Fibonacci numbers
  x \leftarrow c(0, 1, 1, 2, 3, 5, 8)
  # Count how many numbers we have in the vector
  length(x)
[1] 7
  # Calculate the mean of the numbers in the vector
  mean(x)
[1] 2.857143
  # Calculate the median of the numbers in the vector
  median(x)
[1] 2
  # Calculate the standard deviation of the numbers in the vector
  sd(x)
[1] 2.794553
  # Create a new vector of positive integers
  y \leftarrow c(1, 2, 3, 4, 5, 6, 7)
  # Calculate the correlation between vector x and vector y
  cor(x, y)
```

#### [1] 0.938668

#### 1.4.2 Assigning values to variables

1. A variable can be used to store a value. For example, the R code below will store the sales in a variable, say "sales":

```
# Using the assignment operator <-
sales <- 9
# Alternatively, you can use = for variable assignment
sales = 9</pre>
```

- 2. Both  $\leftarrow$  and = can be used for variable assignments.
- 3. R is a case-sensitive language, which means that Sales and sales are considered as two different variables.
- 4. Various operations can be performed using variables in R.

#### {r} # multiply sales by 2 2 \* sales}

```
# Multiply the variable "sales" by 2
2 * sales
```

#### [1] 18

5. We can change the value stored in a variable

```
# Change the value of "sales" to 15
sales <- 15

# Display the revised value of "sales"
sales</pre>
```

#### [1] 15

6. The following R code creates two variables to hold the sales and price of a product, and we can utilize them to compute the revenue:

```
# Variables for sales and price
sales <- 5
price <- 7

# Calculate the revenue using the variables
revenue <- price * sales
revenue</pre>
```

#### [1] 35

R is a powerful and versatile language extensively utilized for data analysis, statistical computing, and creating data visualizations. The provided brief overview aims to acquaint readers with fundamental aspects and capabilities of R, laying the foundation for further exploration and understanding in data analysis and visualization. The ultimate goal is to equip readers with essential knowledge to effectively use R in a variety of data-related tasks and projects.

# 1.5 Summary of Chapter 1 – Getting Started

Chapter 1 provides a comprehensive introduction to the R programming language and its applications, particularly in statistical computations and data analysis. The first part of the chapter presents a basic understanding of R, including its history and development, its usage, and the platforms that support its operation. It discusses how to download and install R and RStudio, considering different operating systems, and it also introduces alternatives like Jupyter Notebook and Visual Studio Code.

The second part delves into the practical aspects of using R, such as conducting mathematical and statistical operations. It provides examples of arithmetic, exponentiation, and logarithmic operations, as well as usage of specific mathematical functions like absolute value, square root, and remainder on division. Moreover, it explains the rounding functions, mean, median, standard deviation, and correlation computations, with examples. The chapter further expounds on the assignment of values to variables in R and the usage of these variables in various operations.

Throughout, the chapter underlines the importance of R in statistical computing, data analysis, and data visualization, emphasizing its versatility and efficiency. The chapter lists a wide range of references for further reading and exploration.

To summarize, this chapter introduces the R programming language, its development, usage, installation process, and various supported platforms. It delves into R's practical applications in mathematical and statistical operations, emphasizing its role in statistical computing, data analysis, and visualization.

# 2 02: Exploring R Packages

Dec 30, 2023.

- 1. R packages are collections of code, data, and documentation that enhance the capabilities of R, a programming language and software environment used for statistical computing and graphics.
- 2. R packages are created by R users and developers and provide additional tools, functions, and datasets that serve various purposes, such as data analysis, visualization, and machine learning.
- 3. R packages can be obtained from various sources, including the Comprehensive R Archive Network (CRAN), Bioconductor, GitHub, and other online repositories.
- 4. To utilize R packages, they can be imported into R using the library() function, allowing access to the functions and data within them for use in R scripts and interactive sessions. [1]

# 2.1 Benefits of R Packages

There are numerous advantages to using R packages:

- 1. **Reusability**: R packages enable users to write code that is readily reusable across applications. Once a package has been created and published, others can install and use it, sparing them time and effort in coding.
- 2. Collaboration: Individuals or teams can develop packages collaboratively, enabling the sharing of code, data, and ideas. This promotes collaboration within the R community and the creation of new tools and techniques.
- 3. **Standardization**: Packages help standardize the code and methodology used for particular duties, making it simpler for users to comprehend and replicate the work of others. This decreases the possibility of errors and improves the dependability of results.
- 4. **Scalability**: Packages can manage large data sets and sophisticated analyses, enabling users to scale up their work to larger, more complex problems.
- 5. **Accessibility**: R packages are freely available and can be installed on a variety of operating systems, making them accessible to a broad spectrum of users. [1]

# 2.2 Comprehensive R Archive Network (CRAN)

- 1. The Comprehensive R Archive Network (CRAN) is a global network of servers dedicated to maintaining and distributing R packages. These packages consist of code, data, and documentation that enhance the functionality of R.
- 2. CRAN serves as a centralized and well-organized repository, simplifying the process for users to find, obtain, and install the required packages. With thousands of packages available, users can utilize the install.packages() function in R to download and install them.
- 3. CRAN categorizes packages into various groups such as graphics, statistics, and machine learning, facilitating easy discovery of relevant packages based on specific needs.
- 4. CRAN is maintained by the R Development Core Team and is accessible to anyone with an internet connection, ensuring broad availability and accessibility. [2]

# 2.3 Installing a R Package

- 1. The install.packages() function can be employed to install R packages.
- 2. For instance, to install the ggplot2 package in R, you would execute the following code:

```
install.packages("ggplot2")
```

- 3. Executing the code provided will download and install the ggplot2 package, along with any necessary dependencies, on your system.
- 4. It's important to remember that a package needs to be installed only once on your system. Once installed, you can easily import the package into your R session using the library() function.
- 5. For example, to import the ggplot2 package in R, you can execute the following code:

#### library(ggplot2)

6. By executing the provided code, you will enable access to the functions and datasets of the ggplot2 package for use within your R session.

#### 2.3.1 Popular R Packages

There are several popular R packages useful for summarizing, transforming, manipulating and visualizing data. Here is a list of some commonly used packages along with a brief description of each:

- 1. dplyr: A grammar of data manipulation, providing a set of functions for easy and efficient data manipulation tasks like filtering, summarizing, and transforming data frames.
- 2. tidyr: Provides tools for tidying data, which involves reshaping data sets to facilitate analysis by ensuring each variable has its own column and each observation has its own row.
- 3. plyr: Offers a set of functions for splitting, applying a function, and combining results, allowing for efficient data manipulation and summarization.
- 4. reshape2: Provides functions for transforming data between different formats, such as converting data from wide to long format and vice versa.
- 5. data.table: A high-performance package for data manipulation, offering fast and memory-efficient tools for tasks like filtering, aggregating, and joining large data sets.
- 6. lubridate: Designed specifically for working with dates and times, it simplifies common tasks like parsing, manipulating, and formatting date-time data.
- 7. stringr: Offers a consistent and intuitive set of functions for working with strings, including pattern matching, string manipulation, and string extraction.
- 8. magrittr: Provides a simple and readable syntax for composing data manipulation and transformation operations, making code more readable and expressive.
- 9. ggplot2: A powerful and flexible package for creating beautiful and customizable data visualizations using a layered grammar of graphics approach.
- 10. plotly: Enables interactive and dynamic data visualizations, allowing users to create interactive plots, charts, and dashboards that can be explored and analyzed. [2]

# 2.4 Sample Plot

As an illustration, here is a sample code for a scatterplot created using the ggplot2 package.

Figure 2.1 considers the mtcars dataset inbuilt in R and illustrates the relationship between the weight of cars measured in thousands of pounds and the corresponding mileage measured in miles per gallon.

```
library(ggplot2)
data(mtcars)

ggplot(mtcars, aes(wt, mpg)) +
   geom_point()
```

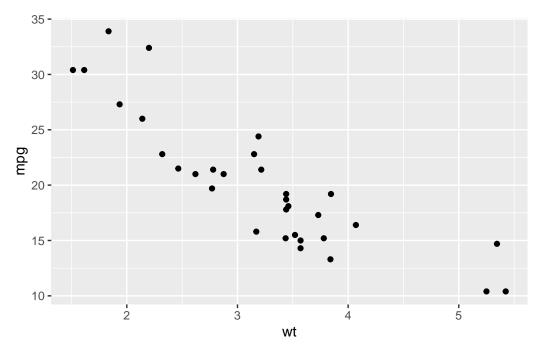

Figure 2.1: Scatterplot of Car Mileage with Car Weight

#### 2.4.1 Getting help

If you require assistance with an R package, there are several avenues you can explore:

- 1. **Documentation**: Most R packages include comprehensive documentation that covers functions, datasets, and usage examples. To access the documentation, you can use the help() function or type ?package\_name directly in the R console, replacing package name with the specific package you want to learn more about.
- 2. **Integrated help system:** R provides an integrated help system that offers documentation and demonstrations for functions and packages. To access this help system, you can use the commands help(topic) or ?topic in the R console, where topic represents the name of the function or package you require assistance with.

3. Online Resources: Numerous online resources are available for obtaining help with R packages. Blogs, forums, and question-and-answer platforms like Stack Overflow offer valuable insights and solutions to specific problems. These platforms are particularly helpful for finding answers to specific questions and obtaining general guidance on package usage. [3]

# 2.5 Summary of Chapter 2 - R Packages

Chapter 2 delves into the world of R packages, explaining what they are, where they can be procured, and how they can be put to use. Defined as clusters of code, data, and relevant documentation, R packages extend the capabilities of R for users. These packages are available from a variety of digital repositories, such as CRAN, Bioconductor, and GitHub, and can be incorporated into R via the library() function.

The advantages of utilizing R packages are manifold, including the ability to reuse and share code, collaborate on development, standardize methodologies, handle large datasets, and operate across different operating systems.

Special emphasis is given to the Comprehensive R Archive Network (CRAN), a central hub for R packages, making it easier for users to find and install the packages they need. The process for installing an R package is detailed, utilizing the install.packages() function, and its subsequent import via the library() function.

The chapter also furnishes a list of well-regarded R packages, each catering to a distinct need, from dplyr for manipulation of data, tidyr for rearranging data, ggplot2 for designing visualizations, among others. A practical example of using the ggplot2 package to generate a scatterplot is provided.

For users who encounter challenges, the chapter recommends consulting the documentation that accompanies each package, making use of the help system built into R, or exploring online resources such as blogs, forums, and Q&A websites. For more extensive understanding, several references are suggested.

# 3 03: Exploring Data Structures

Aug 23, 2023.

The R programming language includes a number of data structures that are frequently employed in data analysis and statistical modeling. These are some of the most popular data structures in R:

- 1. **Vector**: A vector is a one-dimensional array that stores identical data types, such as numeric, character, or logical. The c() function can be used to create vectors, and indexing can be used to access individual vector elements.
- 2. Factor: A factor is a vector representing categorical data, with each distinct value or category represented as a level. Using indexing, individual levels of a factor can be accessed using the factor() function.
- 3. **Dataframe**: A data frame is a two-dimensional table-like structure similar to a spread-sheet, that can store various types of data in columns. The data.frame() function can be used to construct data frames, and individual elements can be accessed using row and column indexing.
- 4. **Matrix**: A matrix is a two-dimensional array of data with identical rows and columns. The matrix() function can be used to construct matrices, and individual elements can be accessed using row and column indexing.
- 5. **Array**: An array is a multidimensional data structure that can contain data of the same data type in user-specified dimensions. Arrays can be constructed using the **array()** function, and elements can be accessed using multiple indexing.
- 6. **List**: A list is an object that may comprise elements of various data types, including vectors, matrices, data frames, and even other lists. The list() function can be used to construct lists, while indexing can be used to access individual elements.

These data structures are helpful for storing and manipulating data in R, and they can be utilized in numerous applications, such as statistical analysis and data visualization. We will focus our attention on Vectors, Factors and Dataframes, since we believe that these are the three most useful data structures. [1]

#### 3.1 Vectors

- 1. A vector is a fundamental data structure in R that can hold a sequence of values of the same data type, such as integers, numeric, character, or logical values.
- 2. A vector can be created using the c() function.
- 3. R supports two forms of vectors: atomic vectors and lists. Atomic vectors are limited to containing elements of a single data type, such as numeric or character. Lists, on the other hand, can contain elements of various data types and structures. [1]

#### 3.1.1 Vectors in R

1. The following R code creates a numeric vector, a character vector and a logical vector respectively.

```
# Read data into vectors
names <- c("Ashok", "Bullu", "Charu", "Divya")
ages <- c(72, 49, 46, 42)
weights <- c(65, 62, 54, 51)
income <- c(-2, 8, 19, 60)
females <- c(FALSE, TRUE, TRUE, TRUE)
```

- 2. The c() function is employed to combine the four character elements into a single vector.
- 3. Commas separate the elements of the vector within the parentheses.
- 4. Individual elements of the vector can be accessed via indexing, which utilizes square brackets []. For instance, names [1] returns Ashok, while names [3] returns Charu.
- 5. We can also perform operations such as categorizing and filtering on the entire vector. For instance, sort(names) returns a vector of sorted names, whereas names[names!="Bullu"] returns a vector of names excluding Bullu.

#### 3.1.2 Vector Operations

Vectors can be used to perform the following vector operations:

1. **Accessing Elements:** We can use indexing with square brackets to access individual elements of a vector. To access the second element of the names vector, for instance, we can use:

```
names[2]
```

#### [1] "Bullu"

- This returns Bullu, the second element of the people vector.
- 2. **Concatenation:** The c() function can be used to combine multiple vectors into a single vector. For instance, to combine the names and ages vectors into the "people" vector, we can use:

```
persons <- c(names, ages)
persons</pre>
```

- [1] "Ashok" "Bullu" "Charu" "Divya" "72" "49" "46" "42"
  - This generates an eight-element vector containing the names and ages of the four people.
  - 3. **Subsetting:** We can use indexing with a logical condition to construct a new vector that contains a subset of elements from an existing vector. For instance, to construct a new vector named female\_names containing only the female names, we can use:

```
female_names <- names[females == TRUE]
female_names</pre>
```

- [1] "Bullu" "Charu" "Divya"
  - This generates a new vector comprising three elements containing the names of the three females Bullu, Charu, and Divya.
  - 4. **Arithmetic Operations:** We can perform element-wise arithmetic operations on vectors.

```
# Addition
addition <- ages + weights
print(addition)</pre>
```

## [1] 137 111 100 93

```
# Subtraction
subtraction <- ages - weights
print(subtraction)</pre>
```

[1] 7 -13 -8 -9

```
# Multiplication
multiplication <- ages * weights
print(multiplication)</pre>
```

[1] 4680 3038 2484 2142

```
# Division
division <- ages / weights
print(division)</pre>
```

[1] 1.1076923 0.7903226 0.8518519 0.8235294

```
# Exponentiation
exponentiation <- ages^2
print(exponentiation)</pre>
```

## [1] 5184 2401 2116 1764

- We perform addition, subtraction, multiplication, division, and exponentiation on these vectors using the arithmetic operators +, -, \*, /, and ^ respectively.
- R also supports other arithmetic operations such as modulus, integer division, and absolute value:

```
# Modulus
modulus <- ages %% income
print(modulus)</pre>
```

[1] 0 1 8 42

```
# Integer Division
integer_division <- ages %/% income
print(integer_division)</pre>
```

[1] -36 6 2 0

```
# Absolute Value
absolute_value <- abs(ages)
print(absolute_value)</pre>
```

#### [1] 72 49 46 42

• R also supports additional arithmetic operations:

```
# Floor Division
floor_division <- floor(ages / income)
print(floor_division)</pre>
```

## [1] -36 6 2 0

• floor calculates the largest integer not exceeding the quotient.

```
# Ceiling Division
ceiling_division <- ceiling(ages / income)
print(ceiling_division)</pre>
```

## [1] -36 7 3 1

• ceiling calculates the smallest integer not less than the quotient.

```
# Logarithm
logarithm <- log(ages)
print(logarithm)</pre>
```

#### [1] 4.276666 3.891820 3.828641 3.737670

• log calculates the natural logarithm of each element.

```
# Square Root
square_root <- sqrt(ages)
print(square_root)</pre>
```

## [1] 8.485281 7.000000 6.782330 6.480741

• sqrt calculates the square root of all the elements.

```
# Sum
sum_total <- sum(ages)
print(sum_total)</pre>
```

## [1] 209

- sum calculates the sum of all the elements.
- 5. **Logical Operations:** We can perform logical operations on vectors, which are also executed element-by-element.

```
# Equality comparison
age_equal_46 <- (ages == 46)
print(age_equal_46)</pre>
```

#### [1] FALSE FALSE TRUE FALSE

• Equality Comparison (==): It checks if the elements of the ages vector are equal to 46. The resulting vector, age\_equal\_46, contains TRUE for elements that are equal to 46 and FALSE otherwise.

```
# Inequality comparison
weight_not_equal_54 <- (weights != 54)
print(weight_not_equal_54)</pre>
```

## [1] TRUE TRUE FALSE TRUE

• Inequality Comparison (!=): It checks if the elements of the weights vector are not equal to 54. The resulting vector, weight\_not\_equal\_54, contains TRUE for elements that are not equal to 54 and FALSE otherwise.

```
# Greater than Comparison
weight_greaterthan_50 <- (weights > 50)
print(weight_greaterthan_50)
```

## [1] TRUE TRUE TRUE TRUE

• Greater than Comparison (>): It checks if each element of the ages vector is greater than 50. The resulting vector, age\_greater\_50, contains TRUE for elements that satisfy the condition and FALSE otherwise.

```
# Less than or Equal to Comparison
weight_lessthan_54 <- (weights <= 54)
print(weight_lessthan_54)</pre>
```

#### [1] FALSE FALSE TRUE TRUE

• Less than or Equal to Comparison (<=): It checks if each element of the weights vector is less than or equal to 54. The resulting vector, weight\_less\_equal\_54, contains TRUE for elements that satisfy the condition and FALSE otherwise.

```
# Logical AND
female_and_income <- females & (income > 0)
print(female_and_income)
```

#### [1] FALSE TRUE TRUE TRUE

• Logical AND (&): It performs a logical AND operation between the females vector and the condition (income > 0). The resulting vector, female\_and\_income, contains TRUE for elements that satisfy both conditions and FALSE otherwise.

```
# Logical OR
age_or_weight_greater_50 <- (ages > 50) | (weights > 50)
print(age_or_weight_greater_50)
```

## [1] TRUE TRUE TRUE TRUE

• Logical OR (|): It performs a logical OR operation between the conditions (ages > 50) and (weights > 50). The resulting vector, age\_or\_weight\_greater\_50, contains TRUE for elements that satisfy either condition or both.

```
# Logical NOT
not_female <- !females
print(not_female)</pre>
```

#### [1] TRUE FALSE FALSE FALSE

• Logical NOT (!): It negates the values in the females vector. The resulting vector, not\_female, contains TRUE for elements that were originally FALSE and FALSE for elements that were originally TRUE.

```
# Negation
not_female <- !females
print(not_female)</pre>
```

#### [1] TRUE FALSE FALSE FALSE

• Negation (!): It negates the values in the females vector. The resulting vector, not\_female, contains TRUE for elements that were originally FALSE and FALSE for elements that were originally TRUE.

```
# Any True
any_age_greater_50 <- any(ages > 50)
print(any_age_greater_50)
```

#### [1] TRUE

• Any True (any()): It checks if there is at least one TRUE value in the logical vector ages > 50. The result, any\_age\_greater\_50, is TRUE if at least one element in ages is greater than 50 and FALSE otherwise.

```
# All True
all_income_positive <- all(income > 0)
print(all_income_positive)
```

#### [1] FALSE

• All True (all()): It checks if all elements in the logical vector income > 0 are TRUE. The result, all\_income\_positive, is TRUE if all values in the income vector are greater than 0 and FALSE otherwise.

```
# Subset with Logical Vector
female_names <- names[females]
print(female_names)</pre>
```

## [1] "Bullu" "Charu" "Divya"

• Subset with Logical Vector: It uses a logical vector females to subset the names vector. The resulting vector, female\_names, contains only the names where the corresponding element in females is TRUE.

```
# Combined Logical Operation
combined_condition <- (ages > 50 & weights <= 54) | (income > 0 & females)
print(combined_condition)
```

#### [1] FALSE TRUE TRUE TRUE

• Combined Logical Operation: It combines multiple conditions using logical AND (&) and logical OR (|). The resulting vector, combined\_condition, contains TRUE for elements that satisfy the combined condition and FALSE otherwise.

```
# Logical Function anyNA()
has_na <- anyNA(names)
print(has_na)</pre>
```

#### [1] FALSE

• Logical Function anyNA(): It checks if there are any missing values (NA) in the names vector. The result, has\_na, is TRUE if there is at least one NA value and FALSE otherwise.

```
# Logical Function is.na()
is_na <- is.na(ages)
print(is_na)</pre>
```

#### [1] FALSE FALSE FALSE

• Logical Function is.na(): It checks if each element of the ages vector is NA. The resulting vector, is\_na, contains TRUE for elements that are NA and FALSE otherwise.

```
# Finding unique values
unique(ages)
```

## [1] 72 49 46 42

- unique(): It finds the unique values in the ages vector
- 6. **Sorting:** We can sort a vector in ascending or descending order using the **sort()** function. For example, to sort the **ages** vector in descending order, we can use:

```
# Sort in ascending order
sorted_names <- sort(names)
print(sorted_names)

[1] "Ashok" "Bullu" "Charu" "Divya"

# Sort in descending order
sorted_names_desc <- sort(names, decreasing = TRUE)
print(sorted_names_desc)

[1] "Divya" "Charu" "Bullu" "Ashok"</pre>
```

In the above code, we demonstrate sorting the names vector in both ascending and descending order using the sort() function. By default, sort() sorts the vector in ascending order. To sort in descending order, we set the decreasing argument to TRUE.

## 3.1.3 Statistical Operations on Vectors

1. **Length**: The length represents the count of the number of elements in a vector.

```
length(ages)
```

[1] 4

- 2. **Maximum** and **Minimum**: The maximum and minimum values are the vector's greatest and smallest values, respectively.
- 3. **Range**: The range is a measure of the spread that represents the difference between the maximum and minimum values in a vector.

```
min(ages)
[1] 42
max(ages)
```

[1] 72

```
range(ages)
```

## [1] 42 72

- 4. **Mean**: The mean is a central tendency measure that represents the average value of a vector's elements.
- 5. **Standard Deviation**: The standard deviation is a measure of dispersion that reflects the amount of variation in a vector's elements.

```
mean(ages)
```

## [1] 52.25

```
sd(ages)
```

## [1] 13.47529

6. **Median**: The median is a measure of central tendency that represents the middle value of a sorted vector.

```
median(ages)
```

## [1] 47.5

7. **Quantiles**: The quantiles are a set of cut-off points that divide a sorted vector into equal-sized groups.

```
quantile(ages)
```

```
0% 25% 50% 75% 100% 42.00 45.00 47.50 54.75 72.00
```

This will return a set of five values, representing the minimum, first quartile, median, third quartile, and maximum of the four ages.

8. **Standard Error of the Mean**: It calculates the standard error of the mean for the ages vector. The result is stored in se\_ages.

```
# Standard Error of the Mean
se_ages <- sqrt(var(ages) / length(ages))
print(se_ages)</pre>
```

#### [1] 6.737643

9. **Cumulative Sum**: It calculates the cumulative sum of the elements in the ages vector. The cumulative sum is stored in cumulative\_sum\_ages.

```
# Cumulative Sum
cumulative_sum_ages <- cumsum(ages)
print(cumulative_sum_ages)</pre>
```

## [1] 72 121 167 209

10. **Correlation Coefficient**: It calculates the correlation coefficient between the ages and females vectors using the cor() function. T

```
# Correlation Coefficient
correlation_ages_females <- cor(ages, females)
print(correlation_ages_females)</pre>
```

#### [1] -0.9770974

Thus, we note that the R programming language provides a wide range of statistical operations that can be performed on vectors for data analysis and modeling. Vectors are clearly a potent and versatile data structure that can be utilized in a variety of ways.

## 3.1.4 Strings

Here are some common string operations that can be conducted using the provided vector examples.

1. **Substring**: The **substr()** function can be used to extract a substring from a character vector. To extract the first three characters of each name in the "names" vector, for instance, we can use:

```
substring_names <- substr(names, start = 2, stop = 4)
print(substring_names)

[1] "sho" "ull" "har" "ivy"</pre>
```

This returns a new character vector containing three letters of each name.

2. **Concatenation**: Using the paste() function, we can concatenate two or more character vectors into a singular vector. To create a new vector containing the names and ages of the individuals, for instance, we can use:

```
persons <- paste(names, ages)
print(persons)</pre>
```

[1] "Ashok 72" "Bullu 49" "Charu 46" "Divya 42"

```
full_names <- paste(names, "Kumar")
print(full_names)</pre>
```

[1] "Ashok Kumar" "Bullu Kumar" "Charu Kumar" "Divya Kumar"

This will generate a new eight-element character vector containing the name and age of each individual, separated by a space.

3. Case Conversion: The toupper() and tolower() functions can be used to convert the case of characters within a character vector. To convert the "names" vector to uppercase letters, for instance, we can use:

```
toupper(names)
```

[1] "ASHOK" "BULLU" "CHARU" "DIVYA"

This will generate a new character vector with all of the names converted to uppercase.

4. **Pattern Matching:** Using the grep() function, we can search for a pattern within the elements of a character vector.

• To find the names in the "names" vector that contain the letter "a", for instance, we can write the following code, which returns a vector containing the indexes of the "names" vector elements that contain the letter "a":

```
grep("a", names)
```

## [1] 3 4

• The following code returns the text of the "names" vector elements that contain the letter "a":

```
pattern_match <- grep("1", names, value = TRUE)
print(pattern_match)</pre>
```

## [1] "Bullu"

5. String Length:: The nchar() function can be used to find the length of a string.

```
# Length of Strings
name_lengths <- nchar(names)
print(name_lengths)</pre>
```

#### [1] 5 5 5 5

- 6. %in% Operator: It checks if each element in the names vector is present in the specified set of names.
- In this example, the resulting vector, names\_found, contains TRUE for elements that are found in the set and FALSE otherwise.

```
# %in% Operator
names_found <- names %in% c("Ashok", "Charu")
print(names_found)</pre>
```

## [1] TRUE FALSE TRUE FALSE

- 7. **Logical Function ifelse()**: It evaluates a logical condition and returns values based on the condition.
- In this example, we use ifelse() to assign the value "Old" to elements in the age\_category vector where the corresponding element in ages is greater than 50, and "Young" otherwise.

```
# Logical Function ifelse()
age_category <- ifelse(ages > 50, "Old", "Young")
print(age_category)

[1] "Old" "Young" "Young" "Young"
```

# 3.2 Summary of Chapter 3 – Data Structures in R

Chapter 3 navigates through the fundamental data structure in R, the vector, and elucidates various operations that can be conducted on vectors. Vectors in R, either numeric, character, or logical, hold elements of the same type and are instrumental in performing computations and managing data.

The chapter delves into creating vectors with the c() function and applying mathematical operations like addition, subtraction, multiplication, division, exponentiation, and modulus on numeric vectors. It further explains how character vectors can be created, inspected, and manipulated, demonstrating through examples how to alter character case, extract substrings, and concatenate strings.

A key focus of the chapter is on logical vectors and operations such as equality, inequality, greater than, less than, and logical negation. It illustrates how these can be applied to vectors to create conditions and filter data, with functions such as any(), all(), and ifelse(). The discussion expands on how logical vectors are used to subset data, and how the %in% operator and is.na() function operate.

The chapter presents statistical operations on vectors, describing functions to compute length, maximum and minimum values, range, mean, median, standard deviation, and quantiles. Other functionalities like standard error of the mean, cumulative sum, and correlation coefficient are also discussed.

Towards the end, the chapter discusses the usage of strings in vectors, covering operations such as substring extraction, concatenation, case conversion, and pattern matching. It finally introduces the nchar() function to determine the length of strings in a vector.

In essence, Chapter 3 provides a practical exploration of vectors in R, shedding light on their creation, manipulation, and utilization in various operations, from basic mathematical computations to complex statistical functions and string operations. It underscores the versatility of vectors as a vital data structure in R for data analysis and modeling. Further exploration is encouraged with a comprehensive list of references.

# 4 04: Reading Data into R

Aug 09, 2023

Dataframes and Tibbles are frequently employed data structures in R for storing and manipulating data. They facilitate the organization, exploration, and analysis of data.

## 4.1 Dataframes

- 1. A dataframe is a two-dimensional table-like data structure in R that stores data in rows and columns, with distinct data types for each column.
- 2. Similar to a spreadsheet or a SQL table, it is one of the most frequently employed data structures in R. Each column in a data frame is a constant-length vector, and each row represents an observation or case.
- 3. Using the data.frame() function or by importing data from external sources such as CSV files, Excel spreadsheets, or databases, dataframe objects can be created in R.
- 4. dataframe objects have many useful built-in methods and functions for manipulating and summarizing data, including subsetting, merging, filtering, and aggregation. [1]

## 4.1.1 Creating a dataframe using raw data

5. The following code generates a data frame named df containing three columns - names, ages, and heights, and four rows of data for each individual.

```
# Create input data as vectors
names <- c("Ashok", "Bullu", "Charu", "Divya")
ages <- c(72, 49, 46, 42)
heights <- c(170, 167, 160, 166)

# Combine input data into a data.frame
people <- data.frame(Name = names, Age = ages, Height = heights)
# Print the resulting dataframe</pre>
```

## print(people)

```
Name Age Height
1 Ashok 72 170
2 Bullu 49 167
3 Charu 46 160
4 Divya 42 166
```

# 4.2 Reading Inbuilt datasets in R

- 1. R contains a number of built-in datasets that can be accessed without downloading or integrating from external sources. Here are some of the most frequently used built-in datasets in R:
- women: This dataset includes the heights and weights of a sample of 15,000 women.
- mtcars: This dataset contains information on 32 distinct automobile models, including the number of cylinders, engine displacement, horsepower, and weight.
- diamonds: This dataset includes the prices and characteristics of approximately 54,000 diamonds, including carat weight, cut, color, and clarity.
- iris: This data set measures the sepal length, sepal width, petal length, and petal breadth of 150 iris flowers from three distinct species.

## 4.2.1 The women dataset

As an illustration, consider the women dataset inbuilt in R, which contains information about the heights and weights of women. It has just two variables:

- 1. height: Height of each woman in inches
- 2. weight: Weight of each woman in pounds
- 3. The data() function is used to import any inbuilt dataset into R. The data(women) command in R loads the women dataset

#### data(women)

4. The str() function gives the dimensions and data types and also previews the data.

#### str(women)

```
'data.frame': 15 obs. of 2 variables:
$ height: num 58 59 60 61 62 63 64 65 66 67 ...
$ weight: num 115 117 120 123 126 129 132 135 139 142 ...
5. The summary() function gives some summary statistics.

summary(women)
```

height weight :58.0 Min. Min. :115.0 1st Qu.:61.5 1st Qu.:124.5 Median:65.0 Median :135.0 :65.0 :136.7 Mean Mean 3rd Qu.:68.5 3rd Qu.:148.0 :72.0 :164.0 Max. Max.

## 4.2.2 The mtcars dataset

The mtcars dataset inbuilt in R comprises data on the fuel consumption and other characteristics of 32 different automobile models. Here is a concise description of the 11 mtcars data columns:

- 1. mpg: Miles per gallon (fuel efficiency)
- 2. cyl: Number of cylinders
- 3. disp: Displacement of the engine (in cubic inches)
- 4. hp: gross horsepower
- 5. drat: Back axle ratio wt: Weight (in thousands of pounds)
- 6. wt: Weight (in thousands of pounds)
- 7. qsec: 1/4 mile speed (in seconds)
- 8. vs: Type of engine (0 = V-shaped, 1 = straight)
- 9. am: Type of transmission (0 for automatic, 1 for manual)
- 10. gear: the number of forward gears
- 11. carb: the number of carburetors

```
data(mtcars)
str(mtcars)
```

```
'data.frame':
               32 obs. of 11 variables:
$ mpg : num 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
$ cyl : num 6646868446 ...
$ disp: num
             160 160 108 258 360 ...
$ hp : num
             110 110 93 110 175 105 245 62 95 123 ...
$ drat: num
             3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...
$ wt : num
             2.62 2.88 2.32 3.21 3.44 ...
             16.5 17 18.6 19.4 17 ...
$ qsec: num
$ vs
     : num
             0 0 1 1 0 1 0 1 1 1 ...
$ am : num
            1 1 1 0 0 0 0 0 0 0 ...
$ gear: num 4 4 4 3 3 3 3 4 4 4 ...
$ carb: num 4 4 1 1 2 1 4 2 2 4 ...
```

# 4.3 Reading different file formats into a dataframe

- 1. We examine how to read data into a dataframe in R when the original data is stored in prominent file formats such as CSV, Excel, and Google Sheets.
- 2. Before learning how to accomplish this, it is necessary to comprehend how to configure the Working Directory in R.

## 4.3.1 Working Directory

- 1. The working directory is the location where R searches for and saves files by default.
- 2. By default, when we execute a script or import data into R, R will search the working directory for files.
- 3. Using R's getwd() function, we can examine our current working directory:

```
getwd()
```

[1] "/cloud/project"

- 4. We are running R in the Cloud and hence we are seeing that the working directory is specified as /cloud/project/DataAnalyticsBook101. If we are doing R programming on a local computer, and if our working directory is the Desktop, then we may see a different response such as C:/Users/YourUserName/Desktop.
- 5. Using R's setwd() function, we can change our current working directory. For example, the following code will set our working directory to the Desktop:

```
setwd("C:/Users/YourUserName/Desktop")
```

6. We should choose an easily-remembered and accessible working directory to store our R scripts and data files. Additionally, we should avoid using spaces, special characters, and non-ASCII characters in file paths, as these can cause file handling issues in R. [2]

## 4.3.2 Reading a CSV file into a dataframe

- 1. CSV is the abbreviation for "Comma-Separated Values." A CSV file is a plain text file that stores structured tabular data.
- 2. Each entry in a CSV file represents a record, whereas each column represents a field. The elements in each record are separated by commas (hence the name Comma-Separated Values), semicolons, or tabs.
- 3. Before proceeding ahead, it is imperative that the file that we wish to read is located in the Working Directory.
- 4. Suppose we wish to import a CSV file named mtcars.csv, located in the Working Directory. We can use the read.csv() function, illustrated as follows.

```
df_csv <- read.csv("mtcars.csv")</pre>
```

- 4. In this example, the read.csv() function reads the mtcars.csv file into a data frame named df\_csv.
- 5. If the file is not in the current working directory, the complete file path must be specified in the read.csv() function argument; otherwise, an error will occur.

## 4.3.3 Reading an Excel (xlsx) file into a dataframe

- 1. Suppose we wish to import a Microsoft Excel file named mtcars.xlsx, located in the Working Directory.
- 2. We can use the read excel function in the R package readxl, illustrated as follows.

```
library(readxl)
df_xlsx <- read_excel("mtcars.xlsx")</pre>
```

## 4.3.4 Reading a Google Sheet into a dataframe

- 1. Google Sheets is a ubiquitous cloud-based spreadsheet application developed by Google. It is a web-based application that enables collaborative online creation and modification of spreadsheets.
- 2. We can import data from a Google Sheet into a R dataframe, as follows.
- Consider a Google Sheet whose preferences have been set such that anyone can view it using its URL. If this is not done, then some authentication would become necessary.
- Every Google Sheet is characterized by a unique Sheet ID, embedded within the URL. For example, consider a Google Sheet containing some financial data concerning S&P500 index shares.
- Suppose the Sheet ID is: 11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7tt0CM
- We can use the function gsheet2tbl in package gsheet to read the Google Sheet into a dataframe, as demonstrated in the following code.

```
# Read S&P500 stock data present in a Google Sheet.
library(gsheet)

prefix <- "https://docs.google.com/spreadsheets/d/"
sheetID <- "11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM"

# Form the URL to connect to
url500 <- paste(prefix, sheetID)

# Read the Google Sheet located at the URL into a dataframe called sp500
sp500 <- gsheet2tbl(url500)</pre>
```

• The first line imports the gsheet package required to access Google Sheets into R.

- The following three lines define URL variables for Google Sheets. The prefix variable contains the base URL for accessing Google Sheets, the sheetID variable contains the ID of the desired Google Sheet.
- The paste() function is used to combine the prefix, sheetID variables into a complete URL for accessing the Google Sheet.
- The gsheet2tb1() function from the gsheet package is then used to read the specified Google Sheet into a dataframe called sp500, which can then be analyzed further in R.

## 4.3.5 Joining or Merging two dataframes

- Suppose we have a second S&P 500 data located in a second Google Sheet and suppose that we would like to join or merge the data in this dataframe with the above dataframe sp500.
- The ID of this second sheet is: 1F5KvFATcehrdJuGjYVqppNYC9hEKSww9rXYHCk2g60A
- We can read the data present in this Google Sheet using the following code, similar to the one discussed above, using the following code.

```
# Read additional S&P500 data that is posted in a Google Sheet.
library(gsheet)

prefix <- "https://docs.google.com/spreadsheets/d/"
sheetID <- "1nm688a3GsPM5cadJIwu6zj336WBaduglY9TSTUaM9jk"

# Form the URL to connect to
url <- paste(prefix, sheetID)

# Read the Google Sheet located at the URL into a dataframe called gf
gf <- gsheet2tbl(url)</pre>
```

- We now have two dataframes named sp500 and gf that we wish to merge or join.
- The two dataframes have a column named Stock in common, which will serve as the key, while doing the join.
- The following code illusrates how to merge two dataframes:

```
# merging dataframes
df <- merge(sp500, gf , id = "Stock")</pre>
```

• We now have a new dataframe named df, which contains the data got from merging the two dataframes sp500 and gf.

## 4.4 Tibbles

- 1. A tibble is a contemporary and enhanced variant of a R data frame that is part of the tidyverse package collection.
- 2. Tibbles are created and manipulated using the dplyr package, which provides a suite of functions optimized for data manipulation.
- 3. The following characteristics distinguish a tibble from a conventional data frame:
- 4. Tibbles must always have unique, non-empty column names. Tibbles do not permit the creation or modification of columns using partial matching of column names. Tibbles improve the output of large datasets by displaying by default only a few rows and columns.
- 5. Tibbles have a more consistent behavior for subsetting.
- 6. Here is an example of using the tibble() function from dplyr to construct a tibble:

```
library(dplyr, warn.conflicts = FALSE)
  # Create a tibble
  my_tibble <- tibble(</pre>
    name = c("Ashok", "Bullu", "Charu"),
    age = c(72, 49, 46),
    gender = c("M", "F", "F")
  # Print the tibble
  my_tibble
# A tibble: 3 x 3
          age gender
 name
  <chr> <dbl> <chr>
1 Ashok
           72 M
2 Bullu
           49 F
3 Charu
           46 F
```

• This generates a tibble consisting of three columns (name, age, and gender) and three rows of data. Note that the column names are preserved and the tibble is printed in a compact and legible manner.

## 4.4.1 Converting a dataframe into a tibble using as\_tibble()

```
# Create a data frame
  my_df <- data.frame(</pre>
    name = c("Ashok", "Bullu", "Charu"),
    age = c(72, 49, 46),
    gender = c("M", "F", "F")
  # Convert the data frame to a tibble
  my_tibble <- as_tibble(my_df)</pre>
  # Print the tibble
  my_tibble
# A tibble: 3 x 3
 name
          age gender
  <chr> <dbl> <chr>
1 Ashok
           72 M
2 Bullu
           49 F
3 Charu
           46 F
```

- This assigns the tibble representation of the data frame my\_df to the variable my\_tibble.
- Note that the resulting tibble has the same column names and data as the original data frame, but has the additional characteristics and behaviors of a tibble.

## 4.4.2 Converting a tibble into a dataframe

- 7. A tibble offers several advantages over a data frame in R:
- Large datasets can be printed with greater clarity and precision using Tibbles. By default, they only print the first few rows and columns, making it simpler to read and comprehend the data structure.
- Better subsetting behavior: Tibbles have a more consistent subsetting behavior. This facilitates the subset and manipulation of data without unintended consequences.
- Consistent naming: Tibbles always have column names that are distinct and non-empty. This makes it simpler to refer to specific columns and prevents errors caused by duplicate or unnamed column names.
- More informative errors: Tibbles provides more informative error messages that make it simpler to diagnose and resolve data-related problems.
- Fewer surprises: Tibbles have more stringent constraints than data frames, resulting in fewer surprises and unexpected behavior.

# 4.5 Summary of Chapter 4 - Reading Data in R

In Chapter 4, we continue our exploration of data frames in R, focusing on reading various file formats into a data frame, managing the working directory, merging data frames, and the concept of tibbles, all with the overall objective of effectively reading data into R, for further analysis.

R uses the concept of a working directory to manage files. By default, R looks for and saves files in the working directory. To check the current working directory, we use the <code>getwd()</code> function. We can change the working directory using the <code>setwd()</code> function. It's advisable to choose an easily accessible working directory and avoid using spaces, special characters, and non-ASCII characters in file paths.

We then learn to read various file formats into a data frame. For a CSV file, we use the read.csv() function. Reading an Excel file into a data frame is accomplished using the read\_excel function from the readxl package. We also explored reading data from Google Sheets using the gsheet2tbl function in the gsheet package.

When dealing with multiple data sources, we may need to merge or join two data frames. R provides the merge() function to merge data frames based on a common key.

The final concept introduced in this chapter is tibbles. A tibble is a modern reimagining of the data frame, part of the tidyverse collection of packages. Tibbles are created and manipulated using the dplyr package. Tibbles have several distinct characteristics, such as unique, non-empty column names, better subsetting behavior, and improved output for large datasets. We

learned how to create a tibble using the tibble() function, and convert a data frame to a tibble using the as\_tibble() function, and vice versa with as.data.frame().

In conclusion, this chapter built upon the concept of data frames and tibbles, showing how they can be used as a versatile tool for reading and storing data in various formats and getting ready to further explore the data.

# 5 05: Exploring Dataframes

Aug 24, 2023.

- The mtcars dataset is a readily available set in R, originally sourced from the 1974 Motor Trend US magazine. It includes data related to fuel consumption and 10 other factors pertaining to car design and performance, recorded for 32 vehicles from the 1973-74 model years.
- 1. To load the mtcars dataset in R, use this command:

```
data(mtcars)
```

# 5.1 Reviewing a dataframe

2. View(): This function opens the dataset in a spreadsheet-style data viewer.

```
View(mtcars)
```

3. head(): This function prints the first six rows of the dataframe.

```
head(mtcars)
```

	mpg	cyl	disp	hp	drat	wt	qsec	٧s	$\mathtt{am}$	gear	carb
Mazda RX4	21.0	6	160	110	3.90	2.620	16.46	0	1	4	4
Mazda RX4 Wag	21.0	6	160	110	3.90	2.875	17.02	0	1	4	4
Datsun 710	22.8	4	108	93	3.85	2.320	18.61	1	1	4	1
Hornet 4 Drive	21.4	6	258	110	3.08	3.215	19.44	1	0	3	1
Hornet Sportabout	18.7	8	360	175	3.15	3.440	17.02	0	0	3	2
Valiant	18.1	6	225	105	2.76	3.460	20.22	1	0	3	1

4. tail(): This function prints the last six rows of the dataframe.

## tail(mtcars)

```

```

5. dim(): This function retrieves the dimensions of a dataframe, i.e., the number of rows and columns.

```
dim(mtcars)
```

## [1] 32 11

6. nrow(): This function retrieves the number of rows in the dataframe.

```
nrow(mtcars)
```

## [1] 32

7. ncol(): This function retrieves the number of columns in the dataframe.

```
ncol(mtcars)
```

## [1] 11

8. names(): This function retrieves the column names of a dataframe.

colnames(): This function also retrieves the column names of a dataframe.

```
names(mtcars)
```

```
[1] "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs" "am" "gear" [11] "carb"
```

```
colnames(mtcars)
```

```
[1] "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs" "am" "gear" [11] "carb"
```

# 5.2 Accessing data within a dataframe

- 1. \$: In R, the dollar sign \$ is a unique operator that lets us retrieve specific columns from a dataframe or elements from a list.
- For instance, consider the dataframe mtcars. If we wish to fetch the data from the data column mpg (miles per gallon), we would use the code mtcars\$mpg. This will yield a vector containing the data from the mpg column.

```
# Extract the mpg column in mtcars dataframe as a vector
mpg_vector <- mtcars$mpg
# Print the mpg vector
print(mpg_vector)</pre>
```

```
[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4 [16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7 [31] 15.0 21.4
```

- 2. [[ or [: The usage of \$ is limited since it doesn't support character substitution for dynamic column access inside functions. In such cases, we can use the double square brackets [[ or single square brackets [.
- As an example, suppose we have a character string stored in a variable var as var<-"mpg".</li>
- Here, the code mtcars\\$var will not return the mpg column. However, if we instead use the code mtcars[[var]] or mtcars[var], we will get the mpg column.

```
# Let's say we have a variable var
var <- "mpg"
# Now we can access the mpg column in mtcars dataframe using [[
mpg_data1 <- mtcars[[var]]
print(mpg_data1)</pre>
```

```
[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4 [16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7 [31] 15.0 21.4

# Alternatively, we can use [
    mpg_data2 <- mtcars[, var]
    print(mpg_data2)

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4 [16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7 [31] 15.0 21.4
```

## 5.3 Data Structures

1. str(): This function displays the internal structure of an R object.

```
str(mtcars)
```

2. class(): This function is used to determine the class or data type of an object. It returns a character vector specifying the class or classes of the object.

```
x <- c(1, 2, 3) # Create a numeric vector
class(x) # Output: "numeric"</pre>
```

[1] "numeric"

```
y <- "Hello, My name is Sameer Mathur!" # Create a character vector class(y) # Output: "character"
```

#### [1] "character"

• class(x) returns "numeric" because x is a numeric vector. Similarly, class(y) returns "character" because y is a character vector.

```
z <- data.frame(a = 1:5, b = letters[1:5]) # Create a data frame
class(z) # Output: "data.frame"</pre>
```

#### [1] "data.frame"

• class(z) returns "data.frame" because z is a data frame.

```
sapply(mtcars, class)
```

```
mpg cyl disp hp drat wt qsec vs
"numeric" "numeric" "numeric" "numeric" "numeric" "numeric" "numeric" "numeric"
    am gear carb
"numeric" "numeric" "numeric"
```

## 5.4 Factors

- 1. In R, factors are a specific data type used for representing categorical variables or data with discrete levels or categories. They are employed to store data that has a limited number of distinct values, such as "male" or "female," "red," "green," or "blue," or "low," "medium," or "high."
- 2. Factors in R consist of both values and levels. The values represent the actual data, while the levels correspond to the distinct categories or levels within the factor. Factors are particularly useful for statistical analysis as they facilitate the representation and analysis of categorical data efficiently.
- 3. For example, in order to change the data type of the am, cyl, vs, and gear variables in the mtcars dataset to factors, you can utilize the factor() function. Here's an example demonstrating how to achieve this:

```
# Convert variables to factors
mtcars$am <- factor(mtcars$am)
mtcars$cyl <- factor(mtcars$cyl)
mtcars$vs <- factor(mtcars$vs)
mtcars$gear <- factor(mtcars$gear)</pre>
```

- The code above applies the factor() function to each variable, thereby converting them to factors. By assigning the result back to the respective variables, we effectively change their data type to factors. This conversion retains the original values while establishing levels based on the distinct values present in each variable.
- After executing this code, the am, cyl, vs, and gear data variables in the mtcars dataset will be of the factor data type. And we can verify this by re-running the str() function

## str(mtcars)

```
'data.frame': 32 obs. of 11 variables:

$ mpg : num 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...

$ cyl : Factor w/ 3 levels "4","6","8": 2 2 1 2 3 2 3 1 1 2 ...

$ disp: num 160 160 108 258 360 ...

$ hp : num 110 110 93 110 175 105 245 62 95 123 ...

$ drat: num 3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...

$ wt : num 2.62 2.88 2.32 3.21 3.44 ...

$ qsec: num 16.5 17 18.6 19.4 17 ...

$ vs : Factor w/ 2 levels "0","1": 1 1 2 2 1 2 1 2 2 2 ...

$ am : Factor w/ 2 levels "0","1": 2 2 2 1 1 1 1 1 1 1 ...

$ gear: Factor w/ 3 levels "3","4","5": 2 2 2 1 1 1 1 1 2 2 2 ...

$ carb: num 4 4 1 1 2 1 4 2 2 4 ...
```

- 4. Levels of a factor variable:
- The levels() function can be used to extract the distinct levels or categories of a factor variable.
- For example, after the cyl variable is converted to a factor, the levels() function can be used to extract the distinct levels or categories of that factor. By executing levels(mtcars\\$cyl), we see the levels present in the cyl variable. For example, if the cyl variable has been transformed into a factor with levels "4", "6", and "8", the result of levels(mtcars\$cyl) will be a character vector displaying these three levels:

## levels(mtcars\$cyl)

#### [1] "4" "6" "8"

- It is important to note that the order of the levels in the output corresponds to their appearance in the original data.
- To change the base level of a factor variable in R, we can use the relevel() function. This function allows us to reassign a new base level by rearranging the order of the levels in the factor variable.
- Here's an example of how you can change the base level of a factor variable:

```
# Assuming 'cyl' is a factor variable with levels "4", "6", and "8"
mtcars$cyl <- relevel(mtcars$cyl, ref = "6")</pre>
```

- In the code above, we apply the relevel() function to the cyl variable, specifying ref = "6" to set "6" as the new base level.
- After executing this code, the levels of the mtcars\$cyl factor variable will be reordered, with "6" becoming the new base level. The order of the levels will be "6", "4", and "8" instead of the original order.
- For convenience, we will change the base level back to "4".

```
# Assuming `cyl` is a factor variable with levels "4", "6", and "8"
mtcars$cyl <- relevel(mtcars$cyl, ref = "4")</pre>
```

• droplevels(): This function is helpful for removing unused factor levels. It removes levels from a factor variable that do not appear in the data, reducing unnecessary levels and ensuring that the factor only includes relevant levels.

```
# Assuming `cyl` is a factor variable with levels "4", "6", and "8"
# Check the levels of `cyl` before removing unused levels
levels(mtcars$cyl)
```

## [1] "4" "6" "8"

```
# Remove unused levels from `cyl`
mtcars$cyl <- droplevels(mtcars$cyl)

# Check the levels of `cyl` after removing unused levels
levels(mtcars$cyl)</pre>
```

```
[1] "4" "6" "8"
```

- We apply droplevels() to mtcars\$cyl to remove any unused levels from the factor variable. This function removes factor levels that are not present in the data. In this case all three levels were present in the data and therefore nothing was removed.
- cut(): This function allows us to convert a continuous variable into a factor variable by dividing it into intervals or bins. This is useful when we want to group numeric data into categories or levels.

```
Low Medium High 18 10 4
```

- In the provided code, a new factor variable called mpg\_category is generated based on the mpg (miles per gallon) variable from the mtcars dataset. This is achieved using the cut() function, which segments the mpg values into distinct intervals and assigns appropriate factor labels.
- The cut() function takes several arguments: mtcars\\$mpg represents the variable to be divided; breaks specifies the cutoff points for interval creation. Here, we define three intervals: values up to 20, values between 20 and 30 (inclusive), and values greater than 30. Here, the breaks argument is defined as c(0, 20, 30, Inf) to indicate these intervals; labels assigns labels to the resulting factor levels. In this instance, the labels "Low", "Medium", and "High" are provided to correspond with the respective intervals.
- Having demonstrated how to create the new column mpg\_category, we will now drop this column from the dataframe.

```
# drop the column `mpg_category`
mtcars$mpg_category = NULL
```

# 5.5 Logical operations

Here are some logical operations functions in R.

• subset(): This function returns a subset of a data frame according to condition(s).

```
# Find cars that have cyl = 4 and mpg < 28
subset(mtcars, cyl == 4 & mpg < 22)</pre>
```

```
# Find cars that have wt > 5 or mpg < 15
subset(mtcars, wt > 5 | mpg < 15)</pre>
```

```

                         8 440 230 3.23 5.345 17.42 0 0
                   14.7
                                                            3
                                                                 4
                         8 350 245 3.73 3.840 15.41 0 0
Camaro Z28
                   13.3
```

• which(): This function returns the indexes of a vector's members that satisfy a condition.

```
# Find the indices of rows where mpg > 20
indices <- which(mtcars$mpg > 20)
indices
```

## [1] 1 2 3 4 8 9 18 19 20 21 26 27 28 32

• ifelse(): This function applies a logical condition to a vector and returns a new vector with values depending on whether the condition is TRUE or FALSE.

```
# Create a new column "high_mpg" based on mpg > 20
mtcars$high_mpg <- ifelse(mtcars$mpg > 20, "Yes", "No")
```

• Dropping a column: We can drop a column by setting it to NULL.

```
# Drop the column "high_mpg"
mtcars$high_mpg <- NULL</pre>
```

• all(): If every element in a vector satisfies a logical criterion, this function returns TRUE; otherwise, it returns FALSE.

```
# Check if all values in mpg column are greater than 20
all(mtcars$mpg > 20)
```

#### [1] FALSE

• any(): If at least one element in a vector satisfies a logical criterion, this function returns TRUE; otherwise, it returns FALSE.

```
# Check if any of the values in the mpg column are greater than 20
any(mtcars$mpg > 20)
```

#### [1] TRUE

• Subsetting based on a condition:

The logical expression [] and square bracket notation can be used to subset the mtcars dataset according to one or more conditions.

```
# Subset mtcars based on mpg > 20
mtcars_subset <- mtcars[mtcars$mpg > 20, ]
mtcars_subset
```

```

                                                                3
                                                                     4
Camaro Z28
                          8 350.0 245 3.73 3.840 15.41
                                                                3
                                                                     4
                   13.3
Cadillac Fleetwood 10.4 8 472.0 205 2.93 5.250 17.98
                                                                3
Lincoln Continental 10.4 8 460.0 215 3.00 5.424 17.82 0 0
                                                                3
```

### 5.6 Statistical functions

• mean(): This function computes the arithmetic mean.

```
mean(mtcars$mpg)
```

#### [1] 20.09062

• median(): This function computes the median.

```
median(mtcars$mpg)
```

#### [1] 19.2

• sd(): This function computes the standard deviation.

```
sd(mtcars$mpg)
```

### [1] 6.026948

• var()': This function computes the variance.

```
var(mtcars$mpg)
```

#### [1] 36.3241

• cor(): This function computes the correlation between variables.

```
cor(mtcars$mpg, mtcars$wt)
```

#### [1] -0.8676594

• unique(): This function extracts the unique elements of a vector.

```
unique(mtcars$mpg)
```

```
[1] 21.0 22.8 21.4 18.7 18.1 14.3 24.4 19.2 17.8 16.4 17.3 15.2 10.4 14.7 32.4 [16] 30.4 33.9 21.5 15.5 13.3 27.3 26.0 15.8 19.7 15.0
```

## 5.7 Summarizing a dataframe

#### 5.7.1 Summarizing a continuous data column

1. summary(): This function is a convenient tool to generate basic descriptive statistics for your dataset. It provides a succinct snapshot of the distribution characteristics of your data.

```
summary(mtcars$mpg)
```

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 10.40 15.43 19.20 20.09 22.80 33.90
```

- 2. When applied to a vector or a specific column in a dataframe, it generates the following:
- Min: This represents the smallest recorded value in the mpg column.
- 1st Qu: This indicates the first quartile or the 25th percentile of the mpg column. It implies that 25% of all mpg values fall below this threshold.
- Median: This value signifies the median or the middle value of the mpg column, also known as the 50th percentile. Half of the mpg values are less than this value.
- Mean: This denotes the average value of the mpg column.
- 3rd Qu: This represents the third quartile or the 75th percentile of the mpg column. It shows that 75% of all mpg values are less than this value.
- Max: This indicates the highest value observed in the mpg column.

- When we use summary(mtcars\$mpg), it returns these six statistics for the mpg (miles per gallon) column in the mtcars dataset.
- When used with an entire dataframe, it applies to each column individually and provides a quick overview of the data.

### 5.7.2 Summarizing a categorical data column

```
summary(mtcars$cyl)
```

4 6 8 11 7 14

• The output of 'summary(mtcars\$cyl)' displays the frequency distribution of the levels within the 'cyl' factor variable. It shows the count or frequency of each level, which in this case are "4", "6", and "8". The summary will provide a concise overview of the distribution of these levels within the dataset.

summary(mtcars)

mpg	cyl	d:	isp		hp	drat
Min. :10.40	4:11	Min.	: 71.1	Min.	: 52.0	Min. :2.760
1st Qu.:15.43	6: 7	1st Qu	.:120.8	1st Qu	.: 96.5	1st Qu.:3.080
Median :19.20	8:14	Median	:196.3	Median	:123.0	Median :3.695
Mean :20.09		Mean	:230.7	Mean	:146.7	Mean :3.597
3rd Qu.:22.80		3rd Qu	.:326.0	3rd Qu	.:180.0	3rd Qu.:3.920
Max. :33.90		Max.	:472.0	Max.	:335.0	Max. :4.930
wt	q	sec	VS	am	gear	carb
Min. :1.513	Min.	:14.50	0:18	0:19	3:15	Min. :1.000
1st Qu.:2.581	1st Qu	.:16.89	1:14	1:13	4:12	1st Qu.:2.000
Median :3.325	Median	:17.71			5: 5	Median :2.000
Mean :3.217	Mean	:17.85				Mean :2.812
3rd Qu.:3.610	3rd Qu	.:18.90				3rd Qu.:4.000
Max. :5.424	Max.	:22.90				Max. :8.000

## 5.8 Creating new functions in R

• We illustrate how to create a custom function in R that computes the mean of any given numeric column in the mtcars dataframe:

```
# Function creation
compute_average <- function(df, column) {
    # Compute the average of the specified column
    average_val <- mean(df[[column]], na.rm = TRUE)

    # Return the computed average
    return(average_val)
}
# Utilize the created function
average_mpg <- compute_average(mtcars, "mpg")
print(average_mpg)

[1] 20.09062

average_hp <- compute_average(mtcars, "hp")
print(average_hp)</pre>
```

#### [1] 146.6875

- In the above code, compute\_average is a custom function which takes two arguments: a dataframe (df) and a column name (as a string) column. The function computes the mean of the specified column in the provided dataframe, with na.rm = TRUE ensuring that NA values (if any) are removed before the mean calculation.
- After defining the function, we utilize it to calculate the average values of the "mpg" and "hp" columns in the mtcars dataframe. These computed averages are then printed.
- Function to calculate average mileage for cars with a specific number of cylinders:

```
avg_mileage_by_cyl <- function(data, cyl) {
   mean(data$mpg[data$cyl == cyl])
}

# Usage

# Returns the average mileage of cars with 4 cylinders
avg_mileage_by_cyl(mtcars, 4)</pre>
```

#### [1] 26.66364

```
# Returns the average mileage of cars with 6 cylinders
avg_mileage_by_cyl(mtcars, 6)
```

[1] 19.74286

## 5.9 Summary of Chapter 5 – Exploring Dataframes

Chapter 5 guides the reader through a comprehensive understanding of data manipulation, logical operations, statistical functions, and custom function creation in R. The chapter highlights a number of significant elements integral to any data analysis task in R.

Firstly, the chapter introduces an essential toolbox for data manipulation in R, focusing on 'dplyr'. It provides a step-by-step tutorial on using key 'dplyr' verbs such as select(), filter(), arrange(), mutate(), and summarise(). The lesson is further enriched with a discussion on the grouping data with the group\_by() function and the application of the pipe operator '%>%', which provides a more readable and organized approach to data manipulation.

Secondly, the chapter explains logical operations in R, demonstrating how they can be employed in subsetting and data extraction tasks. It covers the workings of various functions including subset(), which(), ifelse(), all(), and any(). The chapter elaborates on data subsetting using square brackets and logical expressions, and introduces the sort() and order() functions, essential for arranging data in a particular sequence.

Thirdly, the chapter transitions into an examination of key statistical functions, showcasing the usage of mean(), median(), sd(), var(), and cor(). An interesting aspect is the inclusion of the unique() function, which allows extraction of distinct elements from a vector.

Fourthly, the chapter discusses the utility of the summary() function, providing basic descriptive statistics. This function furnishes a snapshot of dataset characteristics by generating the minimum, 1st quartile, median, mean, 3rd quartile, and maximum values for a specified dataset or column.

Lastly, the chapter unveils how to create and utilize custom functions in R. It provides an in-depth illustration of creating a custom function to calculate the mean of a given numeric column in a dataframe and the average mileage for cars with a specific number of cylinders. These examples highlight the extensibility of R and how custom functions can enhance its capabilities.

In summary, Chapter 5 serves as a comprehensive guide to effectively managing, manipulating, and analyzing data in R. Through the demonstration of custom functions, it underscores how R's functionalities can be extended according to the specific needs of a task, thus, strengthening the flexibility and power of R programming.

# 6 06: Exploring tibbles & dplyr

Sep 08, 2023.

### 6.1 tibbles

A tibble is essentially an updated version of the conventional data frame, providing more flexible and effective data management features (Müller & Wickham, 2021).

Tibbles, also recognized as tbl\_df, are a component of the tidyverse suite, a collection of R packages geared towards making data science more straightforward. They share many properties with regular data frames but also offer unique benefits that enhance our ability to work with data.

- 1. **Printing:** When a **tibble** is printed, only the initial ten rows and the number of columns that fit within our screen's width are displayed. This feature becomes particularly useful when dealing with extensive datasets having multiple columns, enhancing the data's readability.
- 2. **Subsetting:** Unlike conventional data frames, subsetting a tibble always maintains its original structure. Consequently, even when we pull out a single column, it remains as a one-column tibble, ensuring a consistent output type.
- 3. **Data types:** tibbles offer a transparent approach towards data types. They avoid hidden conversions, ensuring that the output aligns with our expectations.
- 4. Non-syntactic names: tibbles support columns having non-syntactic names (those not following R's standard naming rules), which is not always the case with standard data frames.

We consider tibbles to be a vital part of our data manipulation arsenal, especially when working within the tidyverse ecosystem [1].

## 6.2 Basic functions in the dplyr package

The dplyr package is very useful when we are dealing with data manipulation tasks (Wickham et al., 2021). This package offers us a cohesive set of functions, frequently referred to as "verbs," that are designed to facilitate common data manipulation activities. Below, we review some of the key "verbs" provided by the dplyr package:

- 1. **filter():** When we want to restrict our data to specific conditions, we can use **filter()**. For instance, this function allows us to include only those rows in our dataset that fulfill a condition we specify.
- 2. **select():** If we are interested in retaining specific variables (columns) in our data, **select()** is our function of choice. It is particularly useful when we have datasets with many variables, but we only need a select few.
- 3. arrange(): If we wish to reorder the rows in our dataset based on our selected variables, we can use arrange(). By default, arrange() sorts in ascending order. However, we can use the desc() function to sort in descending order.
- 4. mutate(): To create new variables from existing ones, we utilize the mutate() function. It is particularly helpful when we need to conduct transformations or generate new variables that are functions of existing ones.
- 5. **summarise():** To produce summary statistics of various variables, we use **summarise()**. We frequently use it with **group\_by()**, enabling us to calculate these summary statistics for distinct groups within our data.

Moreover, one of the significant advantages of dplyr is the ability to chain these functions together using the pipe operator %>% for a more streamlined and readable data manipulation workflow. [2]

## 6.3 The pipe operator %>%

- 1. The %>% operator, colloquially known as the "pipe" operator, plays a vital role in enhancing the effectiveness of the dplyr package.
- 2. The purpose of this operator is to facilitate a more readable and understandable chaining of multiple operations.
- 3. In a typical scenario in R, when we need to carry out multiple operations on a data frame, each function call must be nested within another. This could lead to codes that are difficult to comprehend due to their complex and nested structure.

4. However, the pipe operator comes to our rescue here. It allows us to rewrite these nested operations in a linear, straightforward manner, greatly enhancing the readability of our code. [3]

## 6.4 Illustration: Using dplyr on mtcars data

### 6.4.1 Loading required R packages

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
```

Aside: When we load the dplyr package using library(dplyr), R displays messages indicating that certain functions from dplyr are masking functions from the stats and base packages. We could instead prevent the display of package startup messages by using suppressPackageStartupMessages(library(dplyr)) or adding library(dplyr, quietly = TRUE, warn.conflicts = FALSE)

### 6.4.2 Reading and Viewing the mtcars dataset as a tibble

```
# Read the mtcars dataset into a tibble called tb
tb <- as_tibble(mtcars)</pre>
```

• The as\_tibble() function is used to convert the built-in mtcars dataset into a tibble object, named tb.

#### Exploring the data:

- The head() function is called on tb to display the first six rows of the dataset. This is a quick way to visually inspect the first few entries.
- The glimpse() function is used to provide a more detailed view of the tb object, showing the column names and their respective data types, along with a few entries for each column.

```
# Display the first few rows of the dataset
head(tb)
```

```
# A tibble: 6 x 11
          cyl
               disp
                        hp drat
                                     wt
                                        qsec
                                                   ٧s
                                                             gear
                                                                    carb
    mpg
                                                         am
  <dbl> <
                                                                   <dbl>
  21
                 160
                       110 3.9
                                   2.62
                                          16.5
                                                                 4
1
                                                    0
                                                          1
  21
                                                                 4
2
            6
                 160
                       110
                             3.9
                                   2.88
                                          17.0
                                                    0
                                                          1
                                                                       4

                                          18.6
                                                    1
                                                          1
                                                                 4
                                                                       1
 21.4
            6
                 258
                       110
                            3.08
                                   3.22
                                          19.4
                                                    1
                                                          0
                                                                 3
                                                                       1
                       175
5 18.7
            8
                 360
                            3.15
                                   3.44
                                          17.0
                                                    0
                                                          0
                                                                 3
                                                                       2
 18.1
            6
                 225
                       105 2.76 3.46
                                          20.2
                                                                 3
                                                                       1
                                                    1
                                                          0
```

# Display the structure of the dataset
glimpse(tb)

#### Changing data types

```
# Convert several numeric columns into factor variables
tb$cyl <- as.factor(tb$cyl)
tb$vs <- as.factor(tb$vs)
tb$am <- as.factor(tb$am)
tb$gear <- as.factor(tb$gear)</pre>
```

- Factors are used in statistical modeling to represent categorical variables.
- The as.factor() function is used to convert the 'cyl', 'vs', 'am', and 'gear' columns from numeric data types to factors.

- In our case, these four variables are better represented as categories rather than numerical values. For instance, 'cyl' represents the number of cylinders in a car's engine, 'vs' is the engine shape, 'am' is the transmission type, and 'gear' is the number of forward gears; all of these are categorical in nature, hence the conversion to factor.
- At this point, we can call the glimpse() function again to review the data structures.

```
# Display the structure of the dataset, again
glimpse(tb)
```

• Notice that the datatypes are now modified and the tibble is ready for futher exploration.

#### 6.4.3 Using dplyr to explore the mtcars tibble

1. **filter():** Recall that this function is used to select subsets of rows in a tibble. It takes logical conditions as inputs and returns only those rows where the conditions hold true. Suppose we wanted to filter the mtcars dataset for rows where the mpg is greater than 25.

```
tb %>%
    filter(mpg > 25)
# A tibble: 6 x 11
               disp
                                        qsec vs
                                                                   carb
    mpg cyl
                        hp drat
                                     wt
                                                     am
                                                           gear
  <dbl> <fct> <dbl> <dbl> <dbl> <dbl> <fct> <fct> <fct> <fct> <fct> <dbl>
1 32.4 4
               78.7
                        66 4.08
                                  2.2
                                         19.5 1

            123 6
# i 22 more rows
```

select(mpg, hp, cyl, am)

tb %>%

- The tibble will only contain the mpg (miles per gallon), hp (horsepower), cyl (cylinders) and am transmission columns selected from the dataset.
- 4. Now suppose we wanted to both filter and select. Specifically, suppose we want to:
- filter cars where the miles per gallon (mpg) are greater than 20 AND number of gears is equal to 5
- select mpg, hp, cyl and am columns for these cars.

```
filterAndSelect <- tb %>%
    filter(mpg > 20 & gear == 5) %>%
    select(mpg, hp, cyl, am)
filterAndSelect

# A tibble: 2 x 4
    mpg    hp cyl    am
    <dbl> <dbl> <fct> <fct>
1    26    91 4    1
2    30.4    113 4    1
```

1 6

110 3.9

2.62

- Here, we have written code that utilizes filter() and select(). These two functions, in concert with the pipe operator (%\>%), create a pipeline of operations for data transformation. Breaking this down, we observe a two-step process:
- filter(mpg > 20 & gear == 5): Here, we are utilizing the filter() function to sift through the dataset tb and retain only those rows where mpg (miles per gallon) is more than 20 and the number of gears is equal to 5.
- select(mpg, hp, cyl, am): This function is then invoked to choose specific columns from our filtered dataset. In this instance, we have picked the columns mpg, hp (horse-power), cyl (cylinders), and am (transmission type). The resulting dataset, therefore, contains only these four columns from the filtered data.
- 5. Suppose we wanted to select all the columns within a range. Specifically, suppose we wanted to select all the columns within cyl and wt, excluding all other columns. Recall that the original tibble has the following data columns.

```
colnames(tb)

[1] "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs" "am" "gear"
[11] "carb"

tb %>%
    select(cyl:wt)

# A tibble: 32 x 5
    cyl disp hp drat wt
    <fct> <dbl> <dbl> <dbl> <dbl> <dbl> </db>
```

```

```

- # i 22 more rows
  - select(cyl:wt): This code selects all columns in the tb dataframe starting from cyl up to and including wt.
  - Only the five columns {cyl, disp, hp, drat, wt} get selected. This is a particularly useful feature when dealing with dataframes that have a large number of columns, and we are interested in a contiguous subset of those columns
  - 6. Alternately, suppose instead that we wanted to select all columns except those within the range of cyl and wt.

```
tb %>%
  select(-cyl:wt)
```

```
# A tibble: 32 x 6
     mpg cyl
                 disp
                              drat
                          hp

                              3.92
                                     3.15
10
    19.2 6
                 168.
                         123
                              3.92
                                    3.44
# i 22 more rows
```

select(-cyl:wt): The - sign preceding the cyl:wt range denotes exclusion. Consequently, this selects all columns in the tb dataframe, excluding those from cyl to wt inclusive.

- 7. **arrange():** Recall that this function is used to reorder rows in a tibble by one or more variables. By default, it arranges rows in ascending order.
- Suppose we want to select only the mpg and hp columns, where hp>200 and we want to sort the result in descending order of mpg.

```
tb %>%
   select(mpg, hp) %>%
   filter(hp>200) %>%
   arrange(desc(mpg))
```

```
# A tibble: 7 x 2
    mpg
           hp
  <dbl> <dbl>
   15.8
          264
2
   15
          335
3
   14.7
          230
  14.3
          245
5
  13.3
          245
6 10.4
          205
7 10.4
          215
```

tb %>% select(mpg, hp): The select function is used here to extract only the mpg and hp columns from the tb dataframe.

filter(hp>200): The filter function is used to extract the cars where horsepower hp>200.

arrange(desc(mpg)): The arrange function is then used to order the rows in descending order (desc) based on the mpg column.

- 8. Benefit from using %>%: Suppose we wanted to subset the data as follows.
- Select cars with 6 cylinders (cyl == 6).
- Choose only the mpg (miles per gallon), hp (horsepower) and wt (weight) columns.
- Arrange in descending order by mpg.

Without using the pipe operator, we would have to nest the operations, as follows:

```
arrange(select(filter(tb, cyl == 6), mpg, hp, wt), desc(mpg))
```

```
# A tibble: 7 x 3
   mpg
          hp
                wt
  <dbl> <dbl> <dbl>
 21.4
         110 3.22
2
  21
         110 2.62
  21
         110 2.88
 19.7
         175 2.77
  19.2
         123 3.44
6 18.1
         105 3.46
         123 3.44
 17.8
```

• Using the pipe operator, we could write the code more efficiently as follows:

```
tb %>%
    filter(cyl == 6) %>%
    select(mpg, hp, wt) %>%
    arrange(desc(mpg))

# A tibble: 7 x 3
    mpg    hp    wt
    <dbl> <dbl> <dbl>
1 21.4 110 3.22
```

- 2 21 110 2.62 3 21 110 2.88
- 4 19.7 175 2.77
- 5 19.2 123 3.44
- 6 18.1 105 3.46
- 7 17.8 123 3.44
  - This way, the pipe operator makes the code more readable and the sequence of operations is easier to follow.
  - 9. mutate(): Recall that this function is used to create new variables (columns) or modify existing ones.
  - Suppose we want to create a new column named efficiency, defined as the ratio of mpg to hp.

```
mutated_data <- tb %>%
  mutate(efficiency = mpg / hp) %>%
  select(mpg, hp, efficiency, cyl, am) %>%
  filter(mpg>30)
```

### mutated\_data

```
# A tibble: 4 x 5
           hp efficiency cyl
    mpg
  <dbl> <dbl>
                    <dbl> <fct>
                                 <fct>
   32.4
                    0.491 4
            66
   30.4
            52
                    0.585 4
                                 1
   33.9
            65
                    0.522 4
3
                                 1
   30.4
                    0.269 4
          113
                                 1
```

- The resulting tibble contains a new column efficiency, which is the ratio of mpg to hp.
- Note that mutate() does not modify the original dataset, but creates a new object mutated\_data with the results. If we want to modify the original dataset, we would need to save the result back to the original variable.

transmute(): This is a variation of mutate() which does not retain the old columns.

- Notice that transmute() retains only the newly created column.
- 10. **summarise():** Recall that this function is used to create summaries of data. It collapses a tibble to a single row. Suppose we want to calculate the mean of mpg in the mtcars dataset

```
tb %>%
  summarise(Mean_mpg = mean(mpg))
```

- This code creates a tibble that contains a single row having the mean value of mpg.
- We can extend this code to print both the Mean and Standard Deviation, by slightly extending the above code, as follows.

11. To include additional statistical measures such as median, quartiles, minimum, and maximum in your summary data, we can use respective R functions within the summarise() function.

```
summary_data <- tb %>% summarise(
    N = n(),
    Mean = mean(mpg),
    SD = sd(mpg),
    Median = median(mpg),
    Q1 = quantile(mpg, 0.25),
    Q3 = quantile(mpg, 0.75),
    Min = min(mpg),
    Max = max(mpg)
  summary_data
# A tibble: 1 x 8
      N Mean
                 SD Median
                               Q1
                                     QЗ
                                          Min
                                                Max
  <int> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <dbl> <
     32 20.1 6.03
                       19.2
                            15.4 22.8 10.4
```

• We could convert this back into a standard dataframe and display it in a better formatted manner up to two decimal places, with the following code.

```
summary_data %>%
  as.data.frame() %>%
  round(2)

N Mean SD Median Q1 Q3 Min Max
```

1 32 20.09 6.03

## 6.5 Additional functions in the dplyr package

19.2 15.43 22.8 10.4 33.9

- 1. rename(): The rename() function is utilized whenever we need to modify the names of some variables in our dataset. Without changing the structure of the original dataset, it allows us to give new names to chosen columns.
- 2. group\_by(): The group\_by() function comes into play when we need to implement operations on individual groups within our data. By categorizing our data based on one or multiple variables, we are able to apply distinct functions to each group separately.
- 3. **slice():** To select rows by their indices, we use the **slice()** function. This is especially handy when we need specific rows, for example, the first 10 or last 10 rows, depending on a defined order.
- 4. **transmute():** When we want to generate new variables from existing ones and keep only these new variables, we use the **transmute()** function. It is similar to **mutate()**, but it only keeps the newly created variables, making it a powerful tool when we're only interested in transformed or calculated variables.
- 5. **pull():** The **pull()** function is used to extract a single variable as a vector from a dataframe. This function becomes very practical when we wish to isolate and work with a single variable outside its dataframe.
- 6. n\_distinct(): To enumerate the unique values in a column or vector, we use the n\_distinct() function. It's an essential function when we want to know the number of distinct elements within a specific categorical variable.

### 6.5.1 Using dplyr to explore the mtcars tibble more

1. **rename():** Remember that this function is helpful in changing column names in our data. For instance, let us modify the name of the mpg column to MPG in the mtcars dataset.

```
tb %>%
    rename(MPG = mpg)
# A tibble: 32 x 11
                                                             gear
     MPG cyl
                 disp
                         hp
                             drat
                                      wt
                                           qsec vs
                                                       am
                                                                     carb
   <dbl> <fct> <dbl> <dbl> <dbl> <dbl> <fct> <fct> <fct> <fct> <dbl>
   21
                 160
                        110
                              3.9
                                    2.62
                                           16.5 0
                                                       1

                                                                        4
                 168.
                                                       0
# i 22 more rows
```

2. group\_by(): This function is key for performing operations within distinct groups of our data.

\*For example, let us group the dataset by cyl (number of cylinders) and am transmission and find the mean and standard deviation for each sub-group.

`summarise()` has grouped output by 'cyl'. You can override using the `.groups` argument.

```
# A tibble: 6 x 4
# Groups:
             cyl [3]
  cyl
               MeanMPG StdDevMPG
        am
  <fct> <fct>
                 <dbl>
                            <dbl>
1 4
        0
                  22.9
                            1.45

                            1.63
4 6
        1
                  20.6
                            0.751
```

```
5 8 0 15.0 2.77
6 8 1 15.4 0.566
```

3. **slice():** Recall that this function is beneficial when we wish to choose rows based on their positions. For example, let us slice from row 3 to row 7 of the dataset.

```
tb %>%
slice(3:7)
```

```
# A tibble: 5 x 11
    mpg cyl
               disp
                        hp drat
                                    wt qsec vs
                                                                  carb
                                                    am
                                                          gear
  <dbl> <fct> <dbl> <dbl> <dbl> <dbl> <fct> <fct> <fct> <fct> <dbl>
  22.8 4
                108
                        93
                           3.85
                                  2.32
                                        18.6 1
                                                    1
                                                          4
                                                                     1
2
  21.4 6
                258
                       110
                            3.08
                                  3.22 19.4 1
                                                    0
                                                          3
                                                                     1
                                                                     2
3
  18.7 8
                360
                       175
                            3.15
                                  3.44
                                        17.0 0
                                                    0
                                                          3
  18.1 6
                                                          3
                225
                       105
                            2.76
                                  3.46
                                        20.2 1
                                                                     1
                                                    0
  14.3 8
                            3.21
                                  3.57
                                        15.8 0
                                                          3
                                                                     4
                360
                       245
```

In this sliced\_data tibble, only the first three rows from the mtcars dataset are included.

4. pull(): Recall that this function is employed to remove a single variable from a dataframe as a vector. Let us isolate the mpg (miles per gallon) variable from the dataset.

```
tb %>%
pull(mpg)
```

- [1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4 [16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7 [31] 15.0 21.4
  - 5. n\_distinct(): Recall that this function is used to count the distinct values in a column or vector. Let us count the number of distinct values in thecyl(cylinders) column from the dataset.

```
tb %>%
summarise(countDistinctCyl = n_distinct(cyl))
```

• This code shows the number of unique levels in the cyl column of the dataset.

## 6.6 Summary of Chapter 7 – Exploring tibbles & dplyr

This chapter has provided an overview of the tibble data structure and the dplyr package in the R programming language.

We started with an introduction to tibble, a data structure in R that is an updated version of data frames with enhanced features for flexible and effective data management. These benefits include more user-friendly printing, reliable subsetting behavior, transparent handling of data types, and support for non-syntactic column names.

Subsequently, we shifted focus to the dplyr package, which is a powerful tool for data manipulation in R. This package offers a cohesive set of functions, often referred to as "verbs", which allow for efficient and straightforward manipulation of data. The key "verbs" in dplyr—filter(), select(), arrange(), mutate(), and summarise()— have been explained and illustrated with examples.

An integral component of the dplyr package, the pipe operator %>%, has also been discussed. This operator allows for a more readable and understandable chaining of multiple operations in R, leading to cleaner and more straightforward code.

The chapter has given a comprehensive illustration of using dplyr on the mtcars dataset. This practical demonstration has involved applying dplyr functions to a dataset and explaining the process and results.

In addition to the basics, the chapter has also touched upon additional dplyr functions such as rename(), group\_by(), and slice(), enriching readers' understanding and competency in data manipulation using R.

Overall, this chapter has provided an in-depth understanding of tibbles and dplyr, their applications, and their importance in data manipulation and management in the R programming environment.

# 7 07: Categorical Data

Sep 4, 2023.

## 7.1 Exploring Univariate Categorical Data

THIS CHAPTER explores how to summarize and visualize univariate, categorical data.

- 1. Categorical data is a type of data that can be divided into categories or groups. labels or categorical codes like "male" and "female," "red," "green," and "blue," or "A," "B," and "C" are frequently used to describe category data. This data type is commonly employed in research and statistics where you can categorize the data under various headings depending on their features, characteristics, or any other parameters [1]
- 2. There are several typical examples of categorical data.:
  - Gender (male, female)
  - Marital status (married, single, divorced)
  - Education level (high school, college, graduate school)
  - Occupation (teacher, doctor, engineer)
  - Hair color (brown, blonde, red, black)
  - Eye color (brown, blue, green, hazel)
  - Type of car (sedan, SUV, truck) [2]

## 7.2 Types of Categorical Data – Nominal, Ordinal Data

1. 'Nominal data': This data type is characterized by variables that have two or more categories without having any kind of order or priority. This name-based categorization means that nominal data represents whether a variable belongs to a certain category or not, but it does not convey any qualitative value about the variable itself. For example, 'gender' is a nominal data type, as it categorizes data into 'male' or 'female', and neither category is intrinsically superior to the other. Nominal data is usually represented by text labels or categorical codes. [2]

- 2. 'Ordinal data': Unlike nominal data, ordinal data categories have an inherent order. This order, however, does not provide any information about the exact differences between the categories. Common examples of ordinal data include the Likert scale in surveys, which ranges from "very dissatisfied" to "very satisfied," or clothing sizes, which are typically "small," "medium," or "large." While we know that "large" is bigger than "medium" and "medium" is bigger than "small," we don't know exactly how much bigger one is compared to the other (McCrum-Gardner, 2008).
  - Ordinal data is frequently utilised to describe groups or categories that can be rated or sorted, such as educational level {high school, college, graduate school}, or movie reviews {G, PG, PG-13, R, NC-17}. [2]

### 7.3 Factor Variables in R

- 1. "Factor" is a term specifically used in R programming language to handle categorical data. Factors are the data objects which are used to categorize the data and store it as levels. They can store both strings and integers. They are useful in data analysis for statistical modeling. [4]
- 2. A factor variable has **levels**, which are the distinct categories of the variable. For instance, if we have a factor variable named "color", the levels might be "red," "blue," and "green." Each level corresponds to a category in the categorical data. Creation of a factor variable in R can be done as follows:

```
color <- c("red", "blue", "green", "red", "green", "yellow")
color_factor <- factor(color)</pre>
```

3. In this example, color\_factor is a factor variable with four levels - "red", "blue", "yellow" and "green".

```
levels(color_factor)
```

```
[1] "blue" "green" "red" "vellow"
```

4. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
# Read the mtcars dataset into a tibble called tb
```

```
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears
# Directly access the data columns of tb, without tb$mpg
attach(tb)</pre>
```

5. The above code reads the mtcars data into a tibble named tb and transforms certain variables from the tibble into factors (categorical variables), using the as.factor() function. Specifically, the cyl (cylinders), vs (engine shape), am (transmission type), and gear (number of gears) variables are transformed into factors. This change is useful for subsequent analyses that need to recognize these variables as categorical data, rather than numerical data.

## 7.4 Analysis of a univariate Factor Variable

- 1. Recall that in the mtcars dataset, cyl stands for the number of cylinders in the car's engine. By transforming cyl into a factor variable, we're recognizing it as a categorical variable, which means we're acknowledging that it consists of several distinct categories or levels. Each category or level corresponds to a specific number of cylinders a car might have. [4]
- 2. Notice that in order to convert cyl into a factor variable in R, we have used the following line of code, which modifies the cyl column in the mtcars data frame (or tibble), transforming it from a numerical variable into a factor variable.

```
tb$cyl <- as.factor(tb$cyl)</pre>
```

- 3. As a univariate factor variable, cyl represents a single, categorical characteristic of each car in the dataset: the number of cylinders in the engine. In this context, "univariate" means that we're only considering one variable at a time, without reference to any other variables. [3]
- 4. In the case of cyl, the unique categories (or levels) would correspond to the different numbers of cylinders in the cars' engines. The following R code give us the levels of cyl.

```
levels(tb$cyl)
```

```
[1] "4" "6" "8"
```

This code could be alternately written as follows, giving the same result:

```
tb$cyl %>% levels()
```

4. The levels() function retrieves the levels of a factor variable. When it is applied to tb\$cyl in the given context, it provides the unique categories of the cyl factor variable from the tb tibble, which are "4", "6", and "8". These values correspond to the distinct number of cylinders in the cars' engines that are represented in the mtcars dataset (Wickham & Grolemund, 2016).

## 7.5 Summarizing a univariate Factor Variable

- 1. Frequency Table: A simple way to summarize categorical (or factor) data is by using a frequency table. It represents the count (frequency) of each category (level) in the factor variable. Essentially, a frequency table gives us a snapshot of the data distribution by indicating how many data points fall into each category [5]
- 2. We can create a frequency table using the table() function. For example, to create a frequency table for the cyl variable in the tb tibble, we could write the following code whose output shows the number of cars that fall into each cyl category (4, 6, or 8 cylinders).

```
table(tb$cyl)
```

4 6 8 11 7 14

This code could be alternately written as follows, giving the same result:

```
tb$cyl %>% table()
```

#### Discussion:

• tb\$cyl: This piece of code is specifying the cyl column in the tb tibble, where cyl represents the number of cylinders in the car's engine.

- %>% table(): The output of tb\$cyl (i.e., the cyl column of tb) is then passed to the table() function via the pipe operator %>%. The table() function creates a frequency table of the cyl column, counting the number of occurrences of each level (i.e., each distinct number of cylinders).
- 3. **Proportions**: In contrast to the table() function, which generates a count of each category, the prop.table() function gives the proportions of each category. The subsequent code computes the proportions of each unique count of cylinders in the cyl column from the tb tibble.

```
tb$cyl %>%
    table() %>%
    prop.table()

.
    4    6    8
0.34375 0.21875 0.43750
```

%>% prop.table(): The output of table(), a frequency table, is passed to the prop.table() function. This function converts the frequency table into a proportion table, showing the proportion of the total for each level rather than the raw count.

• This code could be alternately written as follows, giving the same result.

```
p0 = prop.table(table(cyl))
p0
```

- The prop.table() function is used in this example to determine the percentage of each category in the cyl variable of the mtcars dataset. For example, we find that the proportion of cars with 4 cylinders are 0.34375.
- 4. **Percentages**: Suppose we wanted to express the proportions as percentages, rounded to two decimal places. We could calculate the percentages using the round() function, as follows:

```
tb$cyl %>%
  table() %>%
  prop.table() %>%
  `*`(100) %>%
  round(digits = 2) %>%
  paste0("%")
```

```
[1] "34.38%" "21.88%" "43.75%"
```

#### Discussion:

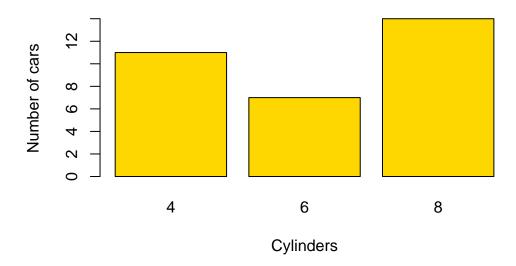

- %>%\*(100): Multiplies these proportions by 100, effectively converting them to percentage format.
- %>% round(digits = 2): Rounds these percentages to two decimal places.
- %>% paste0("%"): Concatenates a % symbol to denote percentages.
- The final output will be a table displaying the percentage of cars that have 4, 6, and 8 cylinders, respectively. Each percentage is rounded to two decimal places. The proportion of each category or group of categories, rounded to two decimal places, is presented. For instance, 43.75% of automobiles have 8 cylinders.

### 7.6 Visualization of a univariate Factor Variable

### 7.6.1 Barplot

- The barplot() function in base R can be used to create a simple bar plot.
- We usually feed it a frequency table, which can be created with the table() function. Here's an example of how to create a bar plot for the cyl variable:

## Number of cars by cylinder count

• In this code, table(tb\$cyl) creates a frequency table for the cyl variable. The xlab, ylab, and main arguments are used to set the x-axis label, y-axis label, and the plot title, respectively. The color of the bars can be altered with the col option.

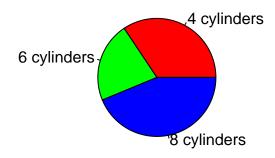

### 7.6.2 Pie chart

- Pie charts can be created with the pie() function in base R.
- Just like with barplot(), we typically provide a frequency table to pie().
- Here's how to create a pie chart for the cyl variable:

```
# Count the number of cars with each number of cylinders
cyl_counts <- table(mtcars$cyl)

# Create a pie chart
pie(cyl_counts,
    main = "Pie Chart of Cars by Number of Cylinders",
    labels = c("4 cylinders", "6 cylinders", "8 cylinders"),
    col = c("red", "green", "blue"))</pre>
```

## Pie Chart of Cars by Number of Cylinders

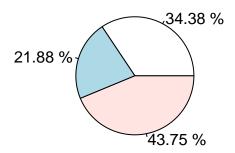

• Alternately, if we wanted to display the percentages, we could write the following code:

```
# Count the number of cars with each number of cylinders
cyl_counts <- table(mtcars$cyl)
percentages <- round(prop.table(table(tb$cyl))*100, 2)
mylabels <- paste(percentages, "%")

# Create a pie chart
pie(cyl_counts,
    main = "Pie Chart of Cars by Number of Cylinders",
    labels = mylabels)</pre>
```

## Pie Chart of Cars by Number of Cylinders

#### **Discussion**:

• percentages <- round(prop.table(table(tb\$cyl))\*100, 2): This line calculates the proportions of each unique number of cylinders, multiplies these proportions by 100 to convert them into percentages, and rounds these percentages to two decimal places. The resulting percentages are saved to the percentages variable.

- mylabels <- paste(percentages, "%"): This line creates labels for each slice of the pie chart. These labels are made up of the percentages calculated in the previous step, followed by a percentage sign (%). The labels are saved to a mylabels variable.
- The pie() function then creates a pie chart using the frequency counts (cyl\_counts) and the labels (mylabels). The main argument is used to set the title of the pie chart.
- While both bar plots and pie charts can be used to visualize the same data, they each have their strengths and limitations. Bar plots are typically better for comparing absolute counts or proportions across levels, whereas pie charts may be more intuitive when demonstrating the part-whole relationship. [7]

## 7.7 Visualization of a univariate Factor data using ggplot2 package

### 7.7.1 Overview of ggplot2 package

- The ggplot2 package, part of the tidyverse collection of R packages, is a powerful and flexible tool for creating a wide range of visualizations in R. It is built on the principles of the Grammar of Graphics, which provides a coherent system for describing and building graphs. [8]
- At the heart of ggplot2 is the idea of mapping data to visual elements. This approach encourages you to think about the relationship between your data and the visual representation, making it easier to create complex and customized graphs.

Key elements of ggplot2 include:

- 1. Data: The data frame that is to be visualized.
- 2. Aesthetics: These are mappings from data to visual elements (like position, color, and size).
- 3. Geoms: Geometric objects that represent the data (like points, lines, and bars).
- 4. Scales: These control how data values are translated to visual elements.
- 5. Facets: For creating multiple sub-plots, each showing a subset of the data.

In a ggplot2 graph, these elements are combined in layers, enabling a high degree of customization. [8]

### 7.7.2 Bar Plot using ggplot2 package

1. Here is an example of how to use ggplot2 to create a bar plot of the cyl factor:

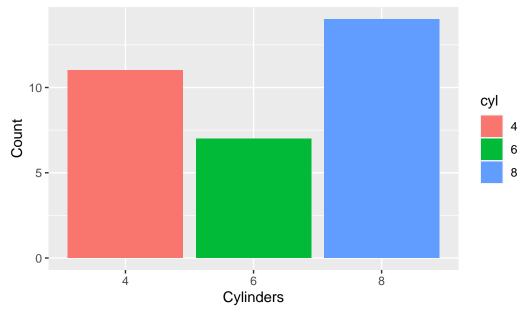

```
library(ggplot2)
```

Attaching package: 'ggplot2'

The following object is masked from 'tb':

mpg

## Bar Plot of Cars by Cylinders

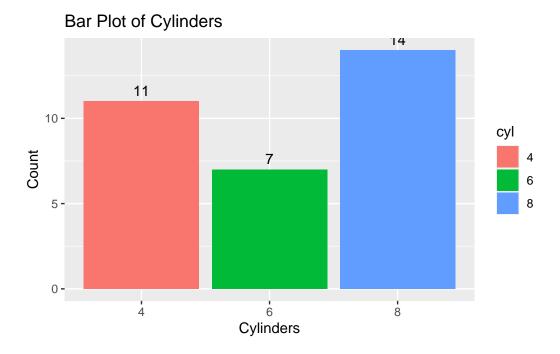

#### Discussion:

- library(ggplot2): This line loads the ggplot2 package into your R session. The ggplot2 package provides a powerful framework for creating diverse and sophisticated graphics in R.
- ggplot(data = tb, aes(x = cyl)) +: This line initiates the creation of a ggplot object. The ggplot() function takes as arguments the data frame to use (tb in this case)

and an aesthetics mapping function aes(), which maps the cyl variable to the x-axis of the plot. The + sign indicates that more layers will be added to this initial ggplot object.

- geom\_bar() +: This line adds a layer to the ggplot object to create a bar plot. The geom\_bar() function by default will create a bar plot where the height of the bars corresponds to the count of each category in the data.
- labs(title = "Bar Plot of Cylinders", x = "Cylinders", y = "Count"): This line adds labels to the plot. The labs() function is used to set the title of the plot and the labels for the x and y axes. The title of the plot is set as "Bar Plot of Cylinders", the x-axis is labeled as "Cylinders", and the y-axis is labeled as "Count".
- To summarize, this code is loading the ggplot2 package, initializing a ggplot object with data from the tb tibble and mapping the cyl variable to the x-axis, adding a bar plot layer to the ggplot object, and finally adding a title and labels to the x and y axes.
- 2. Suppose we wanted to add labels to the bars showing the count of each category. We can do this by using the geom\_text() function in ggplot2. Here's how we can modify our code to include labels:

#### Discussion:

- geom\_text(stat='count', aes(label=after\_stat(count)), vjust=-0.5): This line adds a text layer to the plot.
- The stat='count' argument tells geom\_text() to calculate the count of each category, and aes(label=after stat(count)) maps these counts to the text labels.
- The vjust=-0.5 argument adjusts the vertical position of the labels to be slightly above the top of each bar.
- We can also customize the appearance of the text labels using the various arguments to geom\_text(), such as size, color, fontface, and so on. [8]

#### 7.7.3 Pie chart using ggpie

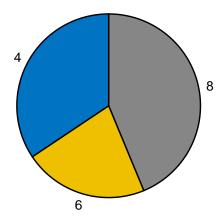

- 1. Aside: Unfortunately, the ggplot2 package doesn't directly support pie charts, because they are generally not as effective at displaying data as other types of plots.
- 2. The ggpie() function is part of the ggpubr package in R, a package that provides a set of functions to enhance the visual appeal and usability of ggplot2 plots It specifically enables the creation of pie charts within the ggplot2 framework. It accepts the following key arguments:
- data: The data frame containing the variables to be used in the pie chart.

- x: The variable in the data frame that determines the size (area) of the pie slices.
- fill: The variable that determines the fill color of the pie slices.
- label: The variable to use for the labels of the slices.
- Additional aesthetic details like the title of the chart, color palette, and other ggplot2 functionalities like adding layers, changing themes, etc., can also be utilized with ggpie().

  [9]
- 3. Let us use ggpie() to create a boxplot of cyl.

# Pie Chart of Cylinders

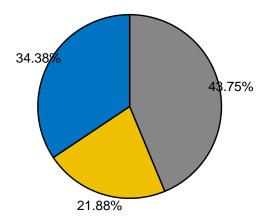

#### Discussion:

- The library(ggpubr) line loads the ggpubr package. This package contains the ggpie function which is used to create pie charts in ggplot2.
- The command table(tb\$cyl) calculates the frequency of each type of cyl (cylinders) present in the tb dataset. as.data.frame() is then used to convert this table into a data frame, which is stored in the cyl\_counts object. The column names of cyl\_counts are then set to "cyl" and "n" using the colnames() function.
- The ggpie() function is used here to generate a pie chart. The arguments to ggpie() specify the data frame (data = cyl\_counts), the variable that determines the size of the pie slices (x = "n"), the variable that determines the fill color of the slices (fill = "cyl"), the variable used for the labels of the slices (label = "cyl"), the color palette (palette = "jco"), and the title of the chart (title = "Pie Chart of Cylinders").
- This code results in a pie chart where each slice represents a different number of cylinders (cyl), the size of each slice is determined by the frequency of each number of cylinders (n), and the color of each slice is determined by the number of cylinders (cyl). The labels for each slice also represent the number of cylinders, and the color palette jco is used for the colors of the slices. [10]
- 4. If we wanted to instead display the percentages for each pie, we could modify this code as follows:

## Pie Chart of Cylinders

#### Discussion:

- This version of the code calculates the proportion of each cylinder type by dividing the count of each type by the total count i.e., cyl\_counts\$n / sum(cyl\_counts\$n).
- These proportions are then stored in a new column in the cyl\_counts data frame.
- Labels are created that display these proportions as percentages, and these labels are used in the pie chart instead of the raw counts.
- The x argument in ggpie() is updated to use these proportions, so the size of each slice in the pie chart corresponds to the proportion of each cylinder type.

# 7.8 Summary of Chapter 8 – Categorical Data

In this chapter, we explored the fundamental concept of categorical data and its two primary types: nominal and ordinal data. Categorical data involves organizing information into distinct categories or groups using labels or codes, making it a crucial data type in various fields, including research, statistics, and data analysis.

We delved into nominal data, which represents variables with categories that lack any inherent order or hierarchy. Examples such as gender (male, female), marital status (married, single, divorced), and hair color (brown, blonde, red, black) exemplify nominal data. These categories are characterized by their name-based grouping, without conveying any intrinsic quantitative information. Next, we discussed ordinal data, which differs from nominal data by possessing

categories with a specific order or ranking, but without exact quantitative distinctions. The Likert scale used in surveys (ranging from "very dissatisfied" to "very satisfied") and clothing sizes (small, medium, large) are instances of ordinal data. While we can determine the order, we lack precise knowledge of the differences between categories.

Factor variables in R played a significant role in the chapter, as they are essential for handling and storing categorical data. Factor variables allow us to map levels to distinct categories, facilitating efficient data organization and manipulation. We learned how to create factor variables in R using the factor() function, which was then applied to the mtcars dataset.

Additionally, we explored the analysis of univariate factor variables in R, focusing on summarizing the data through frequency tables. These tables provided counts of each category, allowing us to understand the distribution of categorical data better. Moreover, we computed proportions and percentages to gain a more insightful view of the data distribution, enhancing the interpretation of results.

The chapter proceeded to introduce powerful visualization techniques for univariate factor variables using the ggplot2 package. As part of the tidyverse collection of R packages, ggplot2 is known for its flexibility and capability to create diverse and customizable visualizations. We specifically looked at creating bar plots using ggplot2. By utilizing the ggplot() function to initialize a ggplot object and the aes() function to map the factor variable to the x-axis, we effectively represented categorical data. The geom\_bar() function enabled the generation of bar plots, while geom\_text() facilitated the addition of count labels for each category, enhancing the visual representation.

Although ggplot2 does not natively support pie charts due to their limited effectiveness in data visualization, we introduced the ggpie() function from the ggpubr package as an alternative. Using ggpie(), we demonstrated how to create pie charts within the ggplot2 framework. The function allowed us to represent proportions or percentages as slices in the pie chart, providing a comprehensive understanding of the distribution of the categorical data.

# 8 08: Categorical x Categorical data (1 of 2)

Sep 10, 2023

## 8.1 Exploring Bivariate Categorical Data

This chapter explores how to summarize and visualize *Bivariate*, categorical data.

- 1. Bivariate analysis involves examining the **relationship between two variables**. For instance, we might examine the relationship between a person's gender (male, female, or non-binary) and whether they own a car (yes or no). By exploring these two categorical variables together, we can discern potential correlations or associations.
- 2. As an extension, multivariate analysis involves the simultaneous observation and analysis of more than two variables. We study multivariate data in the next chapter.
- 3. Contingency Table: A contingency table, also known as a cross-tabulation or crosstab, is a type of table in a matrix format that displays the frequency distribution of the variables. In the case of a univariate factor variable, a contingency table is essentially the same as a frequency table, as there's only one variable involved. In more complex analyses involving two or more variables, contingency tables provide a way to examine the interactions between the variables. [1]
- 4. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears</pre>
```

```
# Directly access the data columns of tb, without tb$mpg
attach(tb)
```

### 8.1.1 Frequency Tables for Bivariate Categorical Data

- 1. As an illustration, let us investigate the bivariate relationship between the number of cylinders (cyl) and whether the car has an automatic or manual transmission, (am=1 for manual, am=0 for automatic).
- 2. table(): We can use this function to generate a contingency table of these two variables.

```
table(tb$cyl, tb$am)
```

```
0 1
4 3 8
6 4 3
```

8 12 2

- In this code, a two-way frequency table of am and cyl is created using the table() function. The frequency of each grouping of categories is displayed in the table that results. As an illustration, there are 8 cars with a manual gearbox and 4 cylinders.
- addmargins(): The addmargins() function is used to add row and/or column totals to a table.

```
table(tb$cyl, tb$am) %>%
  addmargins()
```

```
0 1 Sum

4 3 8 11

6 4 3 7

8 12 2 14

Sum 19 13 32

table(tb$cyl, tb$am) %>%
```

addmargins(1)

```
0 1
4 3 8
6 4 3
8 12 2
Sum 19 13
```

• In this variation, the 1 in the function call indicates that we want to add row totals. So, this command adds the totals (Sum) of each row as a row in the contingency table.

```
table(tb$cyl, tb$am) %>%
  addmargins(2)
```

```
0 1 Sum
4 3 8 11
6 4 3 7
8 12 2 14
```

- In this variation, the 2 specifies that we want to add **column totals**. Thus, it adds the totals (Sum) of each column to the contingency table.
- 3. **xtabs()**: This function provides a more versatile way to generate cross tabulations or contingency tables. It differs from the **table()** function by allowing the use of weights and formulas. Here's how we can use it:

```
am
cyl 0 1
4 3 8
6 4 3
8 12 2
```

- In the code, we have used xtabs() to construct a cross-tabulation of am and cyl.
- The syntax ~ cyl + am is interpreted as a formula, signifying that we aim to cross-tabulate these variables. The output is a table akin to what we obtain with table(), but with the added advantage of accommodating more intricate analyses.

- An important advantage of xtabs() over table() is its superior handling of missing values or NAs; it doesn't automatically exclude them, which is beneficial when dealing with real-world data that often includes missing values. [1]
- 4. **ftable()**: This function is a powerful tool that offers an advanced way to create and display contingency tables. Here's an example of its use:

```
ftable(tb$cyl, tb$am)

0 1

4 3 8
6 4 3
8 12 2
```

- In this code, we've employed the ftable() function to create a contingency table of am and cyl. The output of this function is similar to what we get using table(), but it presents the information in a flat, compact layout, which can be particularly helpful especially when dealing with more than two variables.
- One key advantage of ftable() is that it creates contingency tables in a more readable format when dealing with more than two categorical variables, making it easier to visualize and understand complex multivariate relationships.
- Do note, like xtabs(), ftable() also handles missing values or NAs effectively, making it a reliable choice for real-world data that might contain missing values.
- 5. We can also use group\_by() and summarize() functions from package dplyr to generate contingency tables.

```
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
tb %>%
  group_by(cyl, am) %>%
  summarise(Frequency = n())
```

`summarise()` has grouped output by 'cyl'. You can override using the `.groups` argument.

```
# A tibble: 6 x 3
# Groups: cyl [3]
cyl am Frequency
```

	<fct></fct>	<fct></fct>	<int></int>
1	4	0	3
2	4	1	8
3	6	0	4
4	6	1	3
5	8	0	12
6	8	1	2

## 8.1.2 Proportions Table for Bivariate Categorical Data

6. **prop.table()**: This function is an advantageous tool to understand the relative proportions rather than raw frequencies. It converts a contingency table into a table of proportions. Here is how we could utilize this function:

```
freq <- table(tb$cyl, tb$am)
prop <- prop.table(freq)
round(prop,3)</pre>
```

```
0 1
4 0.094 0.250
6 0.125 0.094
8 0.375 0.062
```

- In this code, we first generate a frequency table with the table() function, using cyl and am as our variables. Then, we employ the prop.table() function to convert this frequency table (freq\_table) into a proportions table (prop\_table).
- This resulting prop\_table reveals the proportion of each combination of cyl and am categories relative to the total number of observations. This can provide insightful context, allowing us to see how each combination fits into the overall distribution. For instance, we could learn what proportion of cars in our dataset have 4 cylinders and a manual transmission.
- Here is a more efficient method of writing the above code using the pipe operator.

```
table(tb$cyl, tb$am) %>%
  prop.table() %>%
  round(3)
```

```
0 1
4 0.094 0.250
6 0.125 0.094
8 0.375 0.062
```

5 8

6 8

0

1

7. We can alternately use package dplyr to showcase the frequency and proportions in tabular form, instead of a contingency table.

```
library(dplyr)
  tb %>%
    group_by(cyl, am) %>%
    summarise(Frequency = n(), .groups = "drop") %>%
    mutate(Proportion = Frequency / sum(Frequency))
# A tibble: 6 x 4
              Frequency Proportion
  cyl
        am
  <fct> <fct>
                  <int>
                             <dbl>
1 4
                            0.0938
        0
                      3
2 4
        1
                      8
                            0.25
3 6
        0
                      4
                            0.125
4 6
                      3
                            0.0938
        1
```

0.375

0.0625

12

2

- In this code, group\_by(cyl, am) groups the data by cyl and am, summarise(Frequency = n()) calculates the frequency for each group, .groups = "drop" drops the grouping structure.
- mutate(Proportion = Frequency / sum(Frequency)) calculates the proportions by dividing each frequency by the total sum of frequencies.
- The mutate() function adds a new column to the dataframe, keeping the original data intact.
- **Percentages and Rounding**: If we wanted to display the proportions as percentages, we could round-off the proportion up to 4 decimal places, as follows:

```
library(dplyr)
tb %>%
  group_by(cyl, am) %>%
  summarise(Frequency = n(), .groups = "drop") %>%
  mutate(Percentage = 100*round(Frequency / sum(Frequency), 4))
```

# A tibble: 6 x 4

	cyl	am	Frequency	Percentage	
	<fct></fct>	<fct></fct>	<int></int>	<dbl></dbl>	
1	4	0	3	9.38	
2	4	1	8	25	
3	6	0	4	12.5	
4	6	1	3	9.38	
5	8	0	12	37.5	
6	8	1	2	6.25	

### 8.1.3 Margins in Proportions Tables

- 1. Different proportions provide various perspectives on the relationship between categorical variables in our dataset. We can calculate the i) Proportions for **Each Cell**; (ii) **Row-Wise\* Proportions**; (iii) **Column-Wise** Proportions. This forms a crucial part of exploratory data analysis.
- 2. Proportions for Each Cell: This calculates the ratio of each cell to the overall total.

```
table(tb$cyl, tb$am) %>%
  prop.table() %>%
  addmargins() %>%
  round(3) %>%
  `*`(100)
```

```
0 1 Sum
4 9.4 25.0 34.4
6 12.5 9.4 21.9
8 37.5 6.2 43.8
Sum 59.4 40.6 100.0
```

3. Row-Wise Proportions: Here, we compute the proportion of each cell relative to the total of its row.

```
table(tb$cyl, tb$am) %>%
  prop.table(1) %>%
  addmargins(2) %>%
  round(3) %>%
  `*`(100)
```

```
0 1 Sum
4 27.3 72.7 100.0
6 57.1 42.9 100.0
8 85.7 14.3 100.0
```

4. **Column-Wise Proportions**: Here, we determine the proportion of each cell relative to the total of its column.

```
table(tb$cyl, tb$am) %>%
  prop.table(2) %>%
  addmargins(1) %>%
  round(3) %>%
  `*`(100)
```

```
0 1
4 15.8 61.5
6 21.1 23.1
8 63.2 15.4
Sum 100.0 100.0
```

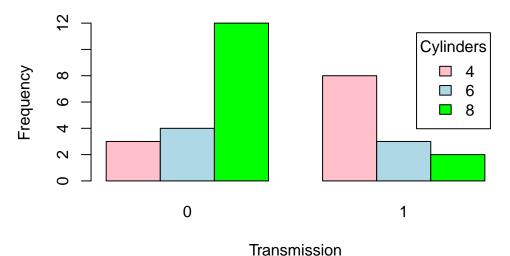

## 8.2 Visualizing Bivariate Categorical Data

- 1. **Grouped Barplots** and **Stacked Barplots** serve as powerful tools for representing and understanding bivariate categorical data, where both variables are categorical in nature.
- 2. Grouped Barplots, often referred to as **side-by-side bar plots**, illustrate the relationship between two categorical variables by placing bars corresponding to one category of a variable next to each other, differentiated by color or pattern. This layout facilitates a direct comparison between categories of the second variable. Grouped bar plots are particularly effective when we are interested in comparing the distribution of a categorical variable across different groups
- 3. On the other hand, **stacked bar plots** present a similar relationship between two categorical variables, but rather than aligning bars side by side, they stack bars on top of one another. This results in a single bar for each category of one variable, with the length of different segments in each bar corresponding to the counts or proportions of the categories of the other variable. Stacked bar plots are advantageous when we're interested in the total size of groups as well as the distribution of a variable across groups. [2]

#### 4. Grouped Barplot

```
# Create a table with count by transmission and number of cylinders
freq <- table(tb$cyl, tb$am)</pre>
freq
   0
     1
  3 8
  4
      3
8 12 2
# Create a Grouped bar plot
barplot(freq,
        beside = TRUE,
        col = c("pink", "lightblue", "green"),
        xlab = "Transmission", ylab = "Frequency",
        main = "Grouped Barplot of Frequency by transmission and cylinders",
        legend.text = rownames(freq),
        args.legend = list(title = "Cylinders"))
```

# Grouped Barplot of Frequency by transmission and cylind-

#### 5. Discussion:

• freq: This is the dataset being visualized, which we anticipate to be a contingency table of am and cyl variables.

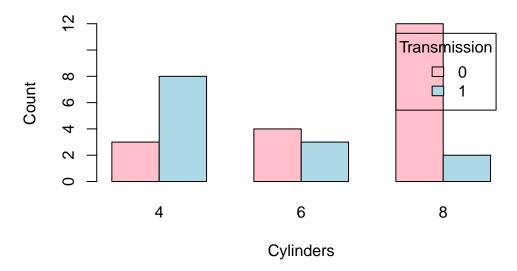

- beside = TRUE: This argument is specifying that the bars should be positioned next to each other, which means that for each level of am, there will be a distinct bar for each level of cyl.
- col = c("pink", "lightblue", "green"): Here, we are setting the colors of the bars to pink, light blue, and green.
- xlab = "Transmission" and ylab = "Frequency": These arguments set the labels for the x and y-axes, respectively.
- main = "Grouped Barplot of Frequency by transmission and cylinders": This argument assigns a title to the plot.
- legend.text = rownames(freq): This creates a legend for the plot, using the row names of freq as the legend text.
- args.legend = list(title = "Cylinders"): This sets the title of the legend to "Cylinders".
- 6. Consider this alternate barplot.

```
# Create a table with count by transmission and number of cylinders
freqInverted <- table(tb$am, tb$cyl)
freqInverted</pre>
```

```
4 6 8
0 3 4 12
1 8 3 2
```

```
# Create the bar plot
barplot(freqInverted,
    beside = TRUE,
    col = c("pink", "lightblue"),
    xlab = "Cylinders", ylab = "Count",
    main = "Grouped Barplot of Frequency by cylinders and transmission",
    legend.text = rownames(freqInverted),
    args.legend = list(title = "Transmission"))
```

## **Grouped Barplot of Frequency by cylinders and transmiss**

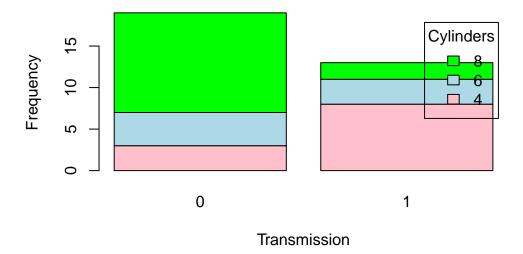

- 5. **Discussion**: The most significant differences from the previous Grouped Barplot and this one are as follows.
- freqInverted: The contingency table's axes have been swapped or inverted. Hence, the table's rows now correspond to the am variable (transmission), and its columns correspond to the cyl variable (cylinders).
- xlab = "Cylinders" and ylab = "Count": These arguments set the labels for the x and y-axes, respectively. This is a departure from the previous plot where the x-axis represented 'Transmission'. In this case, the x-axis corresponds to 'Cylinders'.
- legend.text = rownames(freqInverted) and args.legend = list(title = "Transmission"): In the legend, the roles of 'Transmission' and 'Cylinders' are reversed compared to the previous plot.
- To put it succinctly, the main distinction between the two plots is the swapping of the roles of the cyl and am variables. In the second plot, 'Cylinders' is on the x-axis, which was occupied by 'Transmission' in the first plot. This perspective shift helps to understand the data in a different light, adding another dimension to our exploratory data analysis. [2]

#### 5. Stacked Barplot

```
# Create a table with count by transmission and number of cylinders
freq <- table(tb$cyl, tb$am)
freq</pre>
```

0 1

## Stacked Barplot of Frequency by transmission and cylinde

There are a few key differences between this Stacked Barplot and the original Grouped Barplot:

• beside = FALSE: In the original code, beside = TRUE was used to generate a grouped bar plot, where each set of bars corresponding to each transmission type (automatic or manual) were displayed side by side. However, with beside = FALSE, we obtain a stacked bar plot. In this plot, the bars corresponding to each cylinder category (4, 6, or 8 cylinders) are stacked on top of one another for each transmission type.

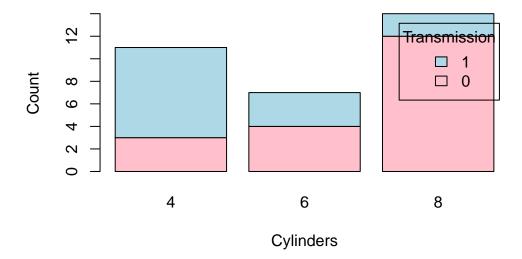

- main = "Stacked Barplot of Frequency by transmission and cylinders": The title of the plot also reflects this change, mentioning now that it's a stacked bar plot instead of a grouped bar plot.
- Finally, here is a Stacked Barplot, corresponding to the second Grouped Barplot discussed above.

```
# Create a table with count by transmission and number of cylinders
freqInverted <- table(tb$am, tb$cyl)
freqInverted</pre>
```

```
4 6 8
0 3 4 12
1 8 3 2
```

```
# Create the bar plot
barplot(freqInverted,
    beside = FALSE,
    col = c("pink", "lightblue"),
    xlab = "Cylinders", ylab = "Count",
    main = "Stacked Barplot of Frequency by cylinders and transmission",
    legend.text = rownames(freqInverted),
    args.legend = list(title = "Transmission"))
```

# Stacked Barplot of Frequency by cylinders and transmissi

6. The grouped bar plot helps in comparing the number of cylinders across transmission types side by side, while the stacked bar plot gives an overall comparison in terms of total number of cars, with the frequency of each cylinder type stacked on top of the other. The choice between a stacked and a grouped bar plot would depend on the specific aspects of the data one would want to highlight. Taken together, grouped and stacked bar plots offer visually appealing and intuitive methods for presenting bivariate categorical data, allowing us to understand and analyze relationships between categorical variables in a meaningful way. [3]

#### 8.2.1 Using ggplot2

### Grouped Barplot using ggplot2

- We demonstrate how to create a Grouped Barplot of Car Count by transmission and cylinders
- 1. Set up the data

```
# Convert the table to a data frame and reshape to 'long' format
freq <- table(tb$cyl, tb$am)
df <- as.data.frame.table(freq)
names(df) <- c("Cylinders", "Transmission", "Frequency")
df$Cylinders <- factor(df$Cylinders)
df$Transmission <- factor(df$Transmission, labels = c("Automatic", "Manual"))</pre>
```

2. Create a Grouped Barplot using ggplot2

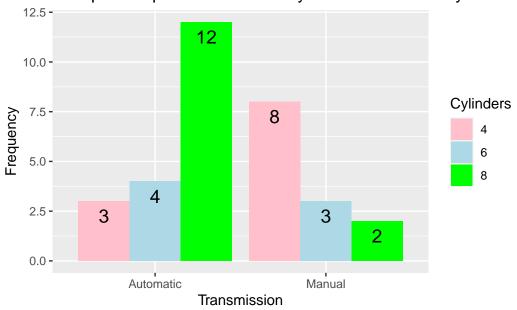

```
# Load required library
library(ggplot2)
```

```
Attaching package: 'ggplot2'
```

The following object is masked from 'tb':

mpg

## Grouped Barplot of Car Count by transmission and cylinders

#### 3. Discussion:

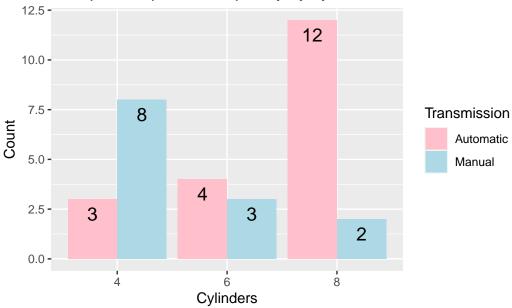

- We first convert the frequency table into a data frame that ggplot2 can use. This involves converting the table to a data frame and then reshaping it to long format.
- We then use the ggplot() function to initiate the plot and specify the aesthetic mappings. Here, we map 'Transmission' to the x-axis, 'Frequency' to the y-axis, and 'Cylinders' to the fill aesthetic which controls the color of the bars.
- geom\_bar() with stat = "identity" is used to add the bar geometry to the plot.
- position = position\_dodge() ensures the bars are placed side by side, which creates the grouped effect.

- labs() is used to add labels to the plot.
- scale\_fill\_manual() allows us to manually specify the colors for the bars.
- We demonstrate how to create a Grouped Barplot of Car Count by cylinders and transmission
- 4. Set up the data

```
freqInverted <- table(tb$am, tb$cyl)
# Convert the table to a data frame and reshape to 'long' format
df_inverted <- as.data.frame.table(freqInverted)
names(df_inverted) <- c("Transmission", "Cylinders", "Count")
df_inverted$Transmission <- factor(df_inverted$Transmission, labels = c("Automatic", "Manudf_inverted$Cylinders <- factor(df_inverted$Cylinders)</pre>
```

5. Create a Grouped Barplot using ggplot2

#### 6. Discussion:

- The geom\_text() function is used in the same way as in the previous example to add frequency labels to the bars.
- The scale\_fill\_manual() function is used to specify the colors for the different transmission types.

#### Stacked Barplots using ggplot2

- We demonstrate how to create a Stacked Barplot of Car Count by cylinders and transmission
- To create a stacked bar plot with ggplot2, we apply the geom\_bar() function but without the dodge positioning this time, since we want the bars stacked.
- 7. Create a Stacked Barplot using ggplot2

```
library(ggplot2)
# Create the Stacked Barplot using ggplot2
ggplot(df, aes(x = Transmission, y = Frequency, fill = Cylinders)) +
   geom_bar(stat = "identity") +
   geom_text(aes(label = Frequency),
        position = position_stack(vjust = 0.5),
        color = "black",
```

```
size = 3.5) +
labs(x = "Transmission", y = "Frequency",
    fill = "Cylinders",
    title = "Stacked Barplot of Frequency by transmission and cylinders") +
scale fill manual(values = c("pink", "lightblue", "green"))
```

## Stacked Barplot of Frequency by transmission and cylinders

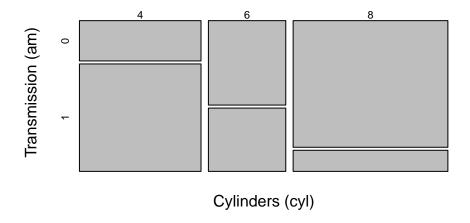

#### 8. Discussion:

- The geom\_bar(stat = "identity") is used to create a stacked bar plot.
- The scale\_fill\_manual() function is used to specify the colors for the different cylinder categories. Again, we changed the order of the Transmission and Cylinders columns to suit this specific plot.
- The geom\_text() function is used to add the labels to the stacked bars. We use position\_stack() to position the labels in the middle of the stacked sections.
- The vjust argument inside position\_stack() controls the vertical positioning of the labels, and 0.5 puts them in the middle.
- As before, scale\_fill\_manual() allows us to specify the colors for the different cylinder categories.

#### 8.2.2 Mosaic Plots for Bivariate Categorical Data

- 1. A mosaic plot is a graphical method for visualizing data from two or more qualitative variables / categorical data. It is a form of area plot that can provide a visual representation of the frequency or proportion of the different categories within the variables.
- 2. The following code generates a mosaic plot from a contingency table of two variables: cyl (cylinders) and am (transmission).

## Mosaic of Cylinder count and Transmission type

- 2. In a mosaic plot, we interpret two categorical variables on two axes.
- The **width** of each section on one axis signifies the proportion of that particular category in our dataset.
- Conversely, the **height** of a section on the other axis illustrates the proportion of that category, contingent on the specific category from the first variable.
- Therefore, the **area** of each rectangle directly corresponds to the frequency or proportion of observations falling within that specific combination of categories (Hartigan & Kleiner, 1981).
- 3. By combining both the height and width of the rectangles, a mosaic plot gives us a visual representation of the joint distribution of the two categorical variables. It helps us to identify patterns, associations, and dependencies between the two variables.

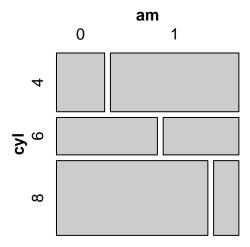

#### 4. Discussion:

- The table() function is used to create a contingency table of the cyl and am columns of the tb tibble. This contingency table represents the counts of all combinations of cyl and am in the data.
- The mosaicplot() function then creates a mosaic plot from this contingency table. The main, xlab, and ylab arguments are used to set the main title, x-axis label, and y-axis label of the plot, respectively.
- This code gives a mosaic plot that visualizes the distribution of the number of cylinders by the type of transmission. Each block's width in the plot would be proportional to the number of cylinders, and the height would be proportional to the transmission type.
- 5. They can be used to identify breaks in independence or test hypotheses regarding the connections between the variables. They are especially helpful for examining interactions between two or more categorical variables.
- 6. The vcd package, short for Visualizing Categorical Data, provides alternative visual and analytical methods for categorical data (Meyer, Zeileis, & Hornik, 2020). A mosaic plot is created from the variables cyl (cylinders) and am (transmission type) using the mosaic() function.

```
# Load the vcd package
library(vcd)
```

#### Loading required package: grid

# Plot of cars by Cylinder count and Transmissi

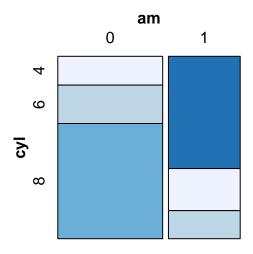

#### 7. Discussion:

- library(vcd) is used to import the vcd package which includes the mosaic() function that is superior to the base R mosaicplot() in its handling of labeling and legends.
- mosaic(\~ cyl + am, data = tb, main = "Mosaic of Cylinder count and Transmission type") creates a mosaic plot.
- In this command, the formula ~ cyl + am tells R to plot cyl against am. The argument data = tb specifies that the variables for the plot come from the tb data frame. The main argument sets the title of the plot.
- 8. We can customize the shading color of the mosaic plot by setting the color using the col argument inside the mosaic() function. To specify shades of blue, we can use the RColorBrewer package and its brewer.pal() function to generate a color palette:

```
shade = TRUE,
highlighting = "cyl",
highlighting fill = cols)
```

# Plots of cars by Cylinder count and Transmiss

#### 9. Discussion:

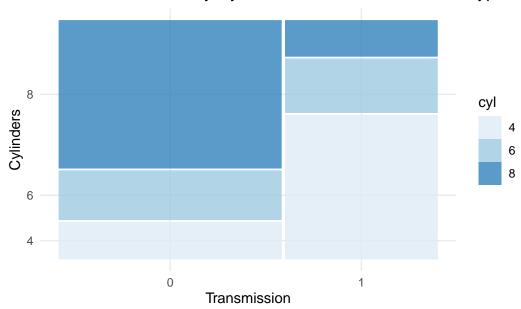

- brewer.pal(4, "Blues") creates a color palette of 4 different shades of blue.
- highlighting = "cyl" means that the shading will differentiate the categories in the cyl variable.
- highlighting\_fill = cols applies the cols color palette to the shading.
- 10. We can also recreate the previous mosaic plot using ggplot2 and ggmosaic packages. Here is how to do it:

```
# Load the packages
library(ggplot2)
library(ggmosaic, quietly = TRUE, warn.conflicts = FALSE)

# Create the mosaic plot
ggplot(data = tb) +
    geom_mosaic(aes(x = product(cyl, am), fill = cyl)) +
    theme_minimal() +
    labs(title = "Mosaic Plot of Cars by Cylinder count and Transmission type",
        x = "Transmission",
        y = "Cylinders") +
```

scale\_fill\_brewer(palette = "Blues")

#### 11. Discussion:

- geom\_mosaic(aes(x = product(cyl, am), fill = cyl)) creates the mosaic plot with cyl and am as the categorical variables.
- The fill = cyl part means that the color fill will differentiate the categories in the cyl variable.
- theme\_minimal() applies a minimal theme to the plot.
- labs() is used to specify the labels for the plot, including the title, x-axis label, and y-axis label.
- scale\_fill\_brewer(palette = "Blues") specifies the color palette to be used for the fill color, in this case, a palette of blues.

# 8.3 Summary of Chapter 9 - Categorical x Categorical data (1 of 2)

In this chapter, we delve into an extensive exploration of various methods for visualizing bivariate categorical data using R, which include but are not limited to grouped bar plots, stacked bar plots, and mosaic plots.

An explanation is provided to distinguish between grouped and stacked bar plots, further supported by the inclusion of coding examples and variations in parameters. Both base R functions and the more advanced ggplot2 library serve as instrumental tools to depict these techniques, furnishing readers with a comprehensive understanding of their practical usage.

The ggplot2 library further elevates the possibilities by offering enhanced customization capabilities and superior control over aesthetics. Detailed coding examples are presented again to explain both the grouped and stacked bar plots within this library.

The chapter also introduces mosaic plots as another way of visualizing bivariate categorical data and discusses how mosaic plots can provide a visual representation of the frequency or proportion of different categories within variables. The use of the base R mosaicplot() function is exemplified, followed by the demonstration of the mosaic() function in the vcd package and the ggmosaic package, bringing full circle the spectrum of visualizations covered for bivariate categorical data.

# 9 09: Categorical x Categorical data (2 of 2)

Sep 10, 2023.

## 9.1 Exploring Multivariate Categorical Data

This chapter explores how to summarize and visualize multivariate, categorical data.

- 1. Multivariate categorical variables allow us to analyze relationships between **three or more** categorical variables respectively.
- 2. This form of analysis can help **reveal complex interactions and dependencies** between multiple variables that cannot be detected in bivariate analyses. Both bivariate and multivariate analyses are essential in statistical and data analysis as they allow us to uncover relationships and patterns in data
- 3. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears
# Directly access the data columns of tb, without tb$mpg
attach(tb)</pre>
```

## 9.2 Three Way Relationships

- 1. A Three-Dimensional Contingency Table, often referred to as a **3-way contingency table**, is a statistical tool that helps analyze the relationship between three categorical variables. It builds upon the concept of a standard two-dimensional contingency table, which shows the distribution of two categorical variables, by adding a third dimension to the analysis.
- 2. Imagine a grid-like structure with three axes representing the three variables. The **rows** correspond to the categories of the first variable, the **columns** represent the categories of the second variable, and the **layers** (sheets) represent the categories of the third variable. Each cell within the table contains the frequency or count of observations that belong to a specific combination of the three variables.
- 3. When dealing with a three-way relationship, our focus is on three categorical variables and how they **interact** with each other. Such interactions can be manifest in the form of changes in the relationship between two variables based on the values of the third variable. Alternatively, we might seek to comprehend how all three variables collectively influence the observed data.
- 4. Graphically, three-way relationships can be represented in various forms, such as **three-dimensional contingency tables**, **side-by-side mosaic plots**, or even **three-dimensional bar plots**. However, it's crucial to note that these visual representations can become complicated and challenging to decipher as the number of categories within each variable rises. [1].

#### 9.2.1 Three-Dimensional Contingency Tables

- 1. The R language, versatile as it is, provides multiple functions for creating contingency tables for multivariate categorical data. In this case, we're focusing on the table(), xtabs(), and ftable() functions for forming a three-way contingency table. [2]
- 2. We can create a three-way contingency table of cyl, gear, and am using the table() function.

```
1
        2
    2
        2
  8 12
        0
 , am = 1
   gear
cyl
           5
        6
           2
  6
     0
        2
           1
  8
     0
        0
           2
```

- When we run this code, the output is a **three-dimensional contingency table** showing the frequencies of all combinations of the three variables. Each cell in the resulting table represents the number of observations for a particular combination of cyl, gear, and am categories.
- Notice that we are segmenting the tables based on the 3rd argument given the table function, which is the transmission am.
- 3. We could alternately run the following code and instead segment the tables based on the cylinders cyl.

```
table(am,
         gear,
         cyl)
 , cyl = 4
   gear
           5
     3
        4
am
     1
        2
           0
     0
        6
           2
, , cyl = 6
   gear
           5
     3
        4
am
  0
     2
        2
           0
     0
        2
           1
  1
, , cyl = 8
```

```
gear
am 3 4 5
0 12 0 0
1 0 0 2
```

4. xtabs(): We can also create a three-way contingency table of cyl, gear, and am using the xtabs() function

```
xtabs(~ cyl + gear + am,
        data = tb)
 , am = 0
  gear
cyl 3
        4
          5
    1
        2
          0
    2
       2 0
 8 12
       0 0
, , am = 1
  gear
cyl 3
    0
        6
          2
    0
        2 1
 6
 8
    0
        0
          2
```

- Here, the formula ~ cyl + gear + am defines the three variables we are interested in.
- 5. ftable(): The ftable() function is employed to generate a 'flat' contingency table, which is essentially a higher-dimensional contingency table displayed in a two-dimensional format. We can also create a three-way contingency table of gear, cyl, and am using the following code:

```
0 1 2 12 2 2 0 0 0 0
1 0 0 0 6 2 0 2 1 2
```

- In this code, ftable(gear + cyl \~ am, data = tb), we arrange the gear and cyl variables in the rows and the am variable in the columns.
- The ~ operator separates the variables that will be displayed in rows (on the left) and columns (on the right) in the resulting table.
- The + operator denotes that both gear and cyl will be included in the row labels. [2]

		gear	3	4	5
cyl	$\mathtt{am}$				
4	0		1	2	0
	1		0	6	2
6	0		2	2	0
	1		0	2	1
8	0		12	0	0
	1		0	0	2

- This variation of code, ftable(gear ~ cyl + am, data = tb), it is structured slightly differently. Here, the gear variable forms the row and both cyl and am variables form the columns of the flat contingency table.
- In both scenarios, a ftable provides a more compact view of the three-way relationship among the gear, cyl, and am variables. However, the orientation of the variables in the rows and columns changes, providing different views of the data and potentially making certain patterns more evident depending on the question we're trying to answer.
- The exact choice between ftable(gear + cyl ~ am, data = tb) and ftable(gear ~ cyl + am, data = tb) will depend on what specific relationships you're most interested in exploring in your data.

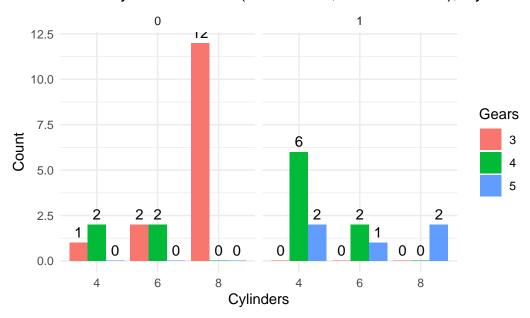

#### 9.2.2 Visualization using a Faceted Bar Plot in ggplot

- 1. A Three-Dimensional Bar Plot is a generalization of a conventional two-dimensional bar graph, expanded into a third dimension. Rather than using bars at specific x coordinates in a two-dimensional plane, we utilize a grid of bars on the x-y plane, extending upwards in the z direction to indicate the data's magnitude. [6]
- 2. Here is some sample code:

```
library(ggplot2)
Attaching package: 'ggplot2'
The following object is masked from 'tb':
    mpg
  # Create a table with count of each combination
  count_df <- table(tb$cyl,</pre>
                     tb$am,
                     tb$gear)
  # Convert table to a data frame for plotting
  count_df <- as.data.frame.table(count_df)</pre>
  # Rename columns
  names(count_df) <- c("cyl", "am", "gear", "count")</pre>
  # Create the plot
  ggplot(count_df,
         aes(x=cyl, y=count,
              fill=gear)) +
    geom_bar(stat="identity",
              position="dodge") +
    facet_grid(~am) +
    labs(
      title = "Count by Transmission (1 = Manual, 0 = Automatic), Cylinders and Gears",
      x = "Cylinders",
      y = "Count",
      fill = "Gears"
    # Add count labels to the bars
    geom_text(aes(label = count),
               position = position_dodge(width = 0.9),
               vjust = -0.5) +
    theme minimal()
```

# Load necessary package

## Count by Transmission (1 = Manual, 0 = Automatic), Cylinders

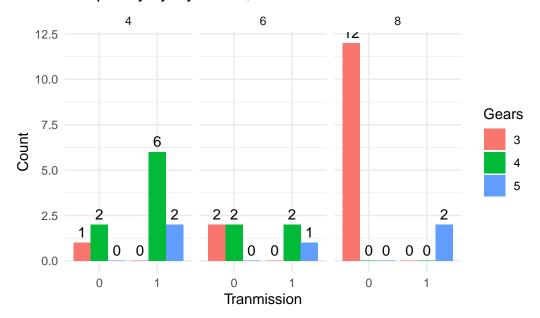

- This code creates a faceted bar plot to visually represent the frequency of combinations of three categorical variables: cyl (Cylinders), am (Transmission), and gear (Gears).
- The line count\_df <- table(tb\$cyl, tb\$am, tb\$gear) generates a contingency table of the frequencies at each level of the three categorical variables (cyl, am, gear), using the table() function.
- Next, count\_df <- as.data.frame.table(count\_df) is used to convert the generated contingency table into a data frame, which can be more conveniently manipulated and visualized using ggplot2. [7]
- The names of the data frame's columns are then reassigned using names(count\_df) <- c("cyl", "am", "gear", "count"). The 'count' column represents the frequency of each combination of the levels of the cyl, am, and gear variables.
- The plot is created using the ggplot() function, which initializes a ggplot object. The aesthetic mapping aes(x=cyl, y=count, fill=gear) specifies that the x-axis represents cyl, the y-axis represents count, and the color fill of the bars is based on gear.
- The geom\_bar(stat="identity", position="dodge") function call adds a layer to the plot that depicts the data as a bar chart. The argument stat="identity" informs ggplot that the heights of the bars are given in the data (i.e., in the count variable), and position="dodge" causes bars associated with different levels of gear to be drawn side-by-side.
- The facet\_grid(~am) function call adds facets to the plot based on the am variable, creating a separate subplot for each level of am.

- The labs() function call specifies the labels for the plot, including the title and the x-, y-, and fill-axis labels. The theme\_minimal() call is used to apply a minimalist aesthetic theme to the plot.
- The aes(label = count) inside geom\_text() tells ggplot to use the count column in the data frame as the labels for each bar. The position\_dodge(width = 0.9) argument ensures that the labels are properly aligned with the corresponding bars in the grouped plot, and vjust = -0.5 adjusts the vertical position of the labels to make them appear just above the bars.
- This code thus provides a clear and insightful visualization of the frequency of each combination of cyl, am, and gear. [7]
- 3. Here is some alternate sample code:

```
# Load necessary package
library(ggplot2)
# Create a table with count of each combination
count df <- table(tb$cyl, tb$am, tb$gear)</pre>
# Convert table to a data frame for plotting
count df <- as.data.frame.table(count df)</pre>
# Rename columns
names(count_df) <- c("cyl", "am", "gear", "count")</pre>
# Create the plot
ggplot(count_df, aes(x=am, y=count, fill=gear)) +
  geom_bar(stat="identity",
           position="dodge") +
  facet_grid(~cyl) +
  labs(
    title = "Frequency by Cylinders, Transmission and Gears",
    x = "Tranmission",
    y = "Count",
    fill = "Gears"
  ) +
   # Add count labels to the bars
  geom_text(aes(label = count),
            position = position_dodge(width = 0.9),
            vjust = -0.5) +
  theme_minimal()
```

## Frequency by Cylinders, Transmission and Gears

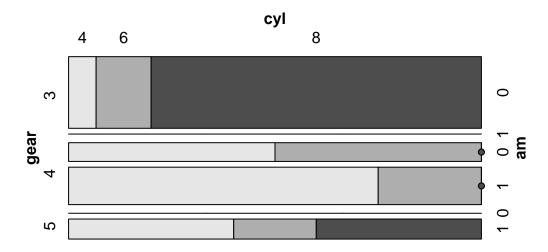

- This code is similar to the previous one; both create a faceted bar plot to display the frequencies of the levels of three categorical variables. The main difference between the two lies in the aesthetic mappings and the facet specification in the ggplot() function call.
- In this new code, the x-axis mapping in aes() is changed from cyl (Cylinders) to am (Transmission). Hence, the x-axis of the bar plot will now depict the Transmission type instead of Cylinders.
- Similarly, the facet\_grid() function, which was previously applied to am, is now applied to cyl. This means that the plot will now be faceted by the Cylinders variable. Each facet (or subplot) will correspond to a different number of Cylinders (4, 6, or 8). [7]

## 9.2.3 Visualization using a Mosaic Plot

# Load necessary packages
library(vcd)

Loading required package: grid

# Mosaic Plot of 3 variables

- 1. The provided R code generates a mosaic plot using the vcd package, specifically focusing on the gear, cyl, and am variables. A mosaic plot is a visual representation of the frequencies or proportions of combinations of categorical variables.
- vcd::mosaic(~gear+cyl+am, data = tb, main = "Mosaic of Gears, Cylinders and Transmission type", shade = TRUE, highlighting = "cyl") generates the mosaic plot. The ~gear+cyl+am formula indicates that the mosaic plot should visualize the gear, cyl, and am variables.
- data = tb specifies the dataset to be used, which is tb in this case.
- main = "Mosaic of Gears, Cylinders and Transmission type" sets the main title of the plot.
- shade = TRUE means that shading is applied to the cells in the plot. The shading can help to differentiate the cells visually based on the residuals from a model of independence.
- highlighting = "cyl" means that the cyl variable's levels will be distinctly colored. This highlighting helps to visually emphasize the differences among cyl categories in the plot. [7]

2. The generated mosaic plot provides an effective visual exploration of the joint distribution of gear, cyl, and am variables in the tb dataset, highlighting the cyl variable.

## 9.3 Four-Way Relationships

• Studying a four-way relationship between four categorical variables, involves looking at their interactions to see how they work together

## 9.3.1 Four-Dimensional Contingency Tables

- 1. Recall that am, cyl, gear, and vs are all categorical / factor variables.
- am indicates the type of transmission (0 = automatic, 1 = manual).
- cyl represents the number of cylinders in the car's engine.
- gear is the number of forward gears in the car.
- vs indicates the engine shape (0 = V-shaped, 1 = straight).
- 2. Suppose we wish to create a 4-way Contingency Table. Recall that the ftable() function provides an easy way to summarize categorical data in a "flat" table, which can make the data easier to understand and interpret. [8]

		am	0			1		
		cyl	4	6	8	4	6	8
gear	٧s							
3	0		0	0	12	0	0	0
	1		1	2	0	0	0	0
4	0		0	0	0	0	2	0
	1		2	2	0	6	0	0
5	0		0	0	0	1	1	2
	1		0	0	0	1	0	0

- In the formula am + cyl ~ gear + vs, the tilde (~) separates the rows and columns of the table.
- The variables to the left of the tilde (am and cyl) form the rows, and the variables to the right of the tilde (gear and vs) form the columns.

- The plus sign (+) between variables indicates that we want to consider all combinations of these variables.
- The resulting table shows the counts of each combination of am and cyl for each combination of gear and vs.
- 4. We can personalize the 4-way contingency table in several ways. Consider this alternate code. [8]

```
0
       am
              4
                                8
                                         4
                                                 6
       cyl
                       6
                                                          8
                   1
                                        0
       vs
gear
3
              0
                                    0
                                        0
                                                 0
                  1
4
              0
                  2
                       0
                           2
                                0
                                    0
                                        0
                                             6
                                                 2
5
                                0
                                    0
                                         1
                                             1
```

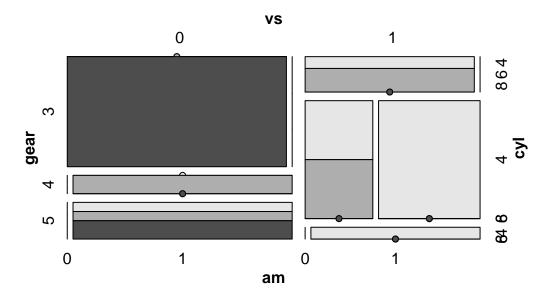

#### 5. Discussion:

- This code ftable(am + cyl + vs ~ gear, data = tb) also uses the ftable function in R to generate a contingency table. However, there is a significant difference in the configuration of variables compared to the previous code.
- In the previous code, am + cyl ~ gear + vs, the row variables (am and cyl) were cross-tabulated against the combinations of column variables (gear and vs).
- In this new code, we have am + cyl + vs ~ gear, which means that we now have three row variables (am, cyl, and vs) and one column variable (gear). This will result in a table showing the counts of each combination of am, cyl, and vs for each level of gear.
- In short, the new code has added vs as a third row variable and removed it from the column variables, thus changing the structure and the interpretation of the resulting table.

## 9.3.2 Visualization using a Mosaic Plot

1. We can visualize four dimensional Contingency Tables using a Mosaic Plot. This is an extension to our previous discussions about two-way and three-way contingency tables. Consider the following code:

# Mosaic Plot of 4 variables

- cyl + vs + gear + am is a formula that indicates the categorical variables to be plotted. Each variable will be represented as a dimension in the plot, and their combined proportions will make up the whole plot.
- The data = tb argument informs the dataframe.
- The main = "Mosaic Plot of 4 variables" line sets the main title of the plot.
- shade = TRUE means that the cells in the mosaic plot will be shaded. The shading adds an extra visual element, which can make it easier to compare proportions.
- Finally, highlighting = "cyl" means that the cells in the plot will be highlighted based on the levels of the cyl variable. This can help to visually differentiate the categories of this variable.

# 9.4 Summary of Chapter 10 – Categorical x Categorical data (2 of 2)

In the third installment of our "Categorical Data" series, we explore the world of multivariate categorical variables. Specifically, we focus on three-dimensional analyses that unveil complex relationships and dependencies between numerous variables.

We utilize the R programming language, demonstrating a range of functions for constructing three-dimensional contingency tables. We also delve into segmenting these tables based on various variables, offering unique perspectives on the data.

Further, we expand on visualizing this data, discussing the creation of three-dimensional bar plots and mosaic plots. These powerful visual tools assist in data interpretation by representing the frequency of combinations of multiple variables.

We don't limit ourselves to three-dimensional analysis; we advance into examining four-way relationships between categorical variables. Here, we utilize four-dimensional contingency tables and mosaic plots for analysis and visualization.

In essence, this chapter provides a robust understanding of multivariate categorical data handling and visualization, preparing readers to navigate and analyze complex datasets effectively.

Overall, these three chapters together provide a comprehensive understanding of handling and visualizing multivariate categorical data.

# **10 10**: Continuous Data (1 of 2)

Aug 8, 2023.

## 10.1 Exploring Univariate Continuous Data

This chapter explores how to summarize and visualize univariate, continuous data.

- 1. Univariate continuous data refers to data coming from one feature or variable, which could take on an infinite number of possible values, typically within an interval [1].
- 2. For instance, in the mtcars dataset in R, variables like mpg (miles per gallon), wt (weight), and hp (horsepower) epitomize continuous data. They are not limited to specific, separate numbers and can encompass any value, including decimal points, within their respective ranges. [2]
- 3. We will leverage the capabilities of R programming and the dplyr package to compute descriptive statistics in order to succinctly represent our data. Further on, the spotlight will be on visualization. With the help of the robust ggplot package, we will create {bee swarm plots, stem-and-leaf plots, histograms, density plots, box plots, violin plots}. These plots will not only represent our univariate continuous data but also facilitate our understanding of data distribution, outliers, and central tendency.
- 4. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears</pre>
```

```
# Directly access the data columns of tb, without tb$mpg
attach(tb)
```

## 10.1.1 Measures of Central Tendency

- 1. In our journey of understanding data, we often turn to certain statistical tools, among which, the measures of central tendency play a pivotal role. These measures provide a way to summarize our data with a single value that represents the "center" or the "average" of our data distribution. [1]
- 2. Primarily, there are three measures of central tendency that we often rely on: the mean, median, and mode. [2]
- 3. As an illustration, here is R code to determine the mean and median of the wt (weight) for all vehicles:

```
# Mean of wt
mean(tb$wt)
```

## [1] 3.21725

```
# Median of wt
median(tb$wt)
```

#### [1] 3.325

5. For finding the mode of the mpg (miles per gallon) column, we use the mfv() function in the modeest package.

```
# Calculate mode of mpg
library(modeest)
mfv(tb$mpg) # Mode
```

## [1] 10.4 15.2 19.2 21.0 21.4 22.8 30.4

6. The mfv() function estimates the mode using a kernel density estimator, which may not always coincide with a specific value in the dataset [4].

## 10.1.2 Measures of Variability

- 1. In our exploration of continuous data, we also consider measures of variability. These statistical measures provide insight into the spread or dispersion of our data points. To further illustrate the concepts we've discussed, we'll apply these measures of variability to the mpg column from the mtcars dataset.
- 2. Range: This is the difference between the highest and the lowest value in our data set. However, while range is easy to calculate and understand, it is sensitive to outliers, so we must interpret it carefully. The range() function in R provides the minimum and maximum mpg.

```
# Range of mpg
range(tb$mpg)
```

## [1] 10.4 33.9

3. **Min and Max**: We can off course measure the minimum and maximum values, using the following simple code.

```
# Minimum mpg
min(tb$mpg)
```

## [1] 10.4

```
# Maximum mpg
max(tb$mpg)
```

## [1] 33.9

4. Variance: It is calculated as the average of the squared deviations from the mean. Larger variances suggest that the data points are more spread out around the mean. One limitation of the variance is that its units are the square of the original data's units, which can make interpretation difficult. We use the var() function to compute the variance.

```
# Variance of mpg
var(tb$mpg)
```

#### [1] 36.3241

5. **Standard Deviation:** This is simply the square root of the variance. Because it is in the same units as the original data, it is often easier to interpret than the variance. A larger standard deviation indicates a greater spread of data around the mean.

```
# Standard Deviation of mpg
sd(tb$mpg)
```

## [1] 6.026948

6. Interquartile Range (IQR): It is another measure of dispersion, especially useful when we have skewed data or outliers. It represents the range within which the central 50% of our data falls. This measure is less sensitive to extreme values than the range, variance, or standard deviation. To find the interquartile range (IQR), which provides the spread of the middle 50% of the mpg values, we use the IQR() function.

```
# Inter-Quartile Range of mpg
IQR(tb$mpg)
```

#### [1] 7.375

- 7. Skewness and Kurtosis:
- Skewness is a measure of the asymmetry of our data. Positive skewness indicates a distribution with a long right tail, while negative skewness indicates a distribution with a long left tail.
- **Kurtosis**, on the other hand, measures the "tailedness" of the distribution. A distribution with high kurtosis exhibits a distinct peak and heavy tails, while low kurtosis corresponds to a flatter shape.
- These two measures can be computed using the skewness() and kurtosis() functions from the moments package.

```
# Load moments package
suppressPackageStartupMessages(library(moments))
# Skewness of 'wt' in the mtcars dataframe
skewness(tb$wt)
```

#### [1] 0.4437855

```
# Kurtosis of 'wt' in the mtcars dataframe
kurtosis(tb$wt)
```

#### [1] 3.172471

8. Overall, these measures of variability help us quantify the dispersion and shape of our data, offering a more complete picture when combined with measures of central tendency. [3]

## 10.2 Summarizing Univariate Continuous Data

- 1. Our primary objective in summarizing data is to gain an initial overview or snapshot of the data set we're dealing with. This fundamental analysis provides us a sense of the data's central tendency, spread, and distribution shape, which in turn guides our decision-making process for subsequent stages of data analysis.
- 2. In R, the summary() function offers a succinct summary of the selected data object. When applied to a numeric vector such as mpg from the mtcars dataset, it yields the minimum and maximum values, the first quartile (25th percentile), the median (50th percentile), the third quartile (75th percentile), and the mean.

```
# A summary of 'mpg'
summary(tb$mpg)

Min. 1st Qu. Median Mean 3rd Qu. Max.
10.40 15.43 19.20 20.09 22.80 33.90
```

3. The describe() function, part of the psych package, goes a step further by providing a more comprehensive summary of the data. It includes additional statistics like the number of valid (non-missing) observations, the standard deviation, and metrics of skewness and kurtosis [5].

```
suppressPackageStartupMessages(library(psych))

# A summary of 'mpg' using describe()
describe(tb$mpg)

vars n mean sd median trimmed mad min max range skew kurtosis se
X1 1 32 20.09 6.03 19.2 19.7 5.41 10.4 33.9 23.5 0.61 -0.37 1.07
```

4. Specific columns from describe(tb\$mpg)

```
# Select specific columns from describe(mpg)
columns = c("n", "mean", "sd", "median", "min", "max", "skew", "kurtosis")
describe(tb$mpg)[, columns]
```

```
n mean sd median min max skew kurtosis
X1 32 20.09 6.03 19.2 10.4 33.9 0.61 -0.37
```

## 10.2.1 Summarizing an entire dataframe or tibble

1. The function summary() in R can also be employed to summarize the entirety of a dataframe or tibble in a comprehensive manner. [3].

```
# A summary of the tibble tb
summary(tb)
```

```
cyl
                              disp
                                                 hp
                                                                 drat
     mpg
                                                 : 52.0
                                                                   :2.760
Min.
       :10.40
                 4:11
                         Min.
                                : 71.1
                                          Min.
                                                           Min.

#### 2. Discussion

• For numeric columns, summary() delivers a six-number summary that includes minimum, first quartile (Q1 or 25th percentile), median (Q2 or 50th percentile), mean, third quartile (Q3 or 75th percentile), and maximum. This gives a broad understanding of the central tendency and dispersion of the data within each numeric column.

- For categorical (factor) columns, summary() generates the counts of each category level. The output of this code is essentially a comprehensive snapshot of the tb tibble, enabling us to quickly understand the nature of our data. [3]
- 3. To obtain a more detailed statistical summary of an entire dataframe or tibble, we can employ the describe() function from the psych package [2].

```
# Select specific columns from describe(mpg)
columns = c("n","mean","sd","median","min","max","skew","kurtosis")
describe(tb)[, columns]
```

```
n
            mean
                      sd median
                                   min
                                           max
                                                skew kurtosis

## 4. Discussion:

- The describe() function analyzes each column in the provided tibble individually and outputs a range of useful statistics. For numeric columns, it offers count, mean, standard deviation, trimmed mean, minimum and maximum values, range, skewness, and kurtosis among others.
- For non-numeric or factor columns, the describe() function still provides a count of
  elements but defaults to NA for the rest of the statistics, as these metrics are not applicable.

## 10.3 Visualizing Univariate Continuous Data

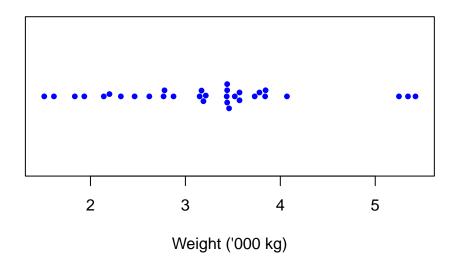

• In our journey to explore and understand univariate continuous data, visualizations act as our valuable companions. Visual graphics provide us with an instant and clear understanding of the underlying data patterns and distributions that may otherwise be challenging to discern from raw numerical data.

- Let's take a closer look at some of the most effective ways of visualizing univariate continuous data, including
- (i) Bee Swarm plots;
- (ii) Stem-and-Leaf plots
- (iii) Histograms;
- (iv) PDF and CDF Density plots;
- (v) Box plots;
- (vi) Violin plots;
- (vii) Quantile-Quantile (Q-Q) Plots

## 10.3.1 Bee Swarm Plot

1. A Bee Swarm plot is a *one-dimensional scatter plot* that reduces overlap and provides a better representation of the distribution of individual data points. This type of plot provides a more detailed view of the data, particularly for smaller data sets. [6]

## **Bee Swarm Plot of Weight (wt)**

#### 2. Discussion

- In the above code, we load the beeswarm package using the library() function.
- We then create a bee swarm plot of the wt column using the beeswarm() function.
- The main argument is used to specify the title of the plot.
- The pch argument is used to set the type of points to be plotted, and the cex argument is used to set the size of the points.
- The col argument is used to set the color of the points.
- The resulting plot displays the individual wt values in the dataset as points on a horizontal axis, with no overlap between points. This provides a visual representation of the distribution of the data, as well as any outliers or gaps in the data.
- horizontal = TRUE: Renders it horizontally rather than the default vertical orientation.

## 10.3.2 Stem-and-Leaf Plot

- 1. Stem-and-leaf plots serve as an efficient tool for visualizing the distribution of data, particularly when working with small to medium-sized datasets. The method involves breaking down each data point into a "stem" and a "leaf", with the "stem" representing the primary digit(s) and the "leaf" embodying the subsequent digit(s) [7]
- 2. We can utilize the stem() function in R to devise stem-and-leaf plots. Here's how we can apply it to the wt column:

```
stem(tb$wt)
```

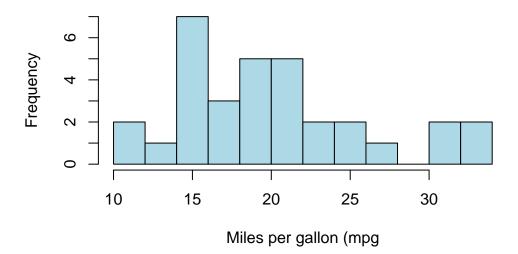

- 3. In the resulting plot, the vertical bar ("|") symbolizes the decimal point's location.
- 4. This visual representation enables us to swiftly assess the data's distribution, the center, and the spread, in a fashion similar to a histogram. However, unlike a histogram, a stem-and-leaf plot retains the original data to a certain degree, providing more granular detail.

## 10.3.3 Histogram

- 1. A histogram is a graphical representation showcasing the *frequency* of discrete or grouped data points within a dataset.
- 2. It splits the data into equal-width bins, with the height of each bar matching the frequency of data points in each respective bin.
- 3. It serves as a valuable tool for demonstrating the distribution shape of the data. In R, we can construct a histogram using the hist() function and control its appearance. The final histogram visually depicts the frequency of mpg values in the dataset, where each bar represents the count of observations within a specific range of values. [7]

```
# Create a histogram of mpg column with a specific number of bins of equal width
hist(tb$mpg,
    breaks = 12, # This creates 12 bins of equal width
    main="Histogram of mpg (with 12 breaks)",
    xlab="Miles per gallon (mpg",
    col="lightblue",
    border="black")
```

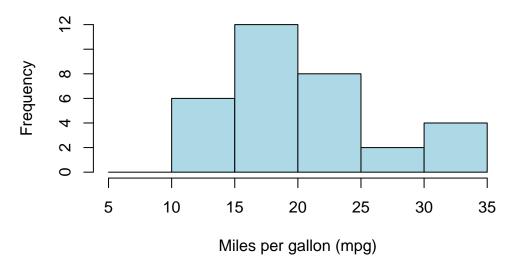

## Histogram of mpg (with 12 breaks)

- This code generates a histogram of mpg using the hist() function. The main argument denotes the plot's title, while the xlab argument labels the x-axis.
- We use the col argument to specify the color of the histogram bars, and the border argument to determine the color of the bar borders.
- We can control the *number of bins* or the ranges of the bins in a histogram using the breaks argument inside the hist() function:
- 5. We can alternately specify the ranges of the bins:

```
# Create a histogram of mpg column with specific bin ranges
hist(tb$mpg,
    breaks = seq(5, 35, by = 5), # This creates bins with ranges 10-15, 15-20, etc.
    main="Histogram of Mileage (with breaks of 5)",
    xlab="Miles per gallon (mpg)",
    col="lightblue",
    border="black")
```

## Histogram of Mileage (with breaks of 5)

#### 6. Discussion:

- The breaks argument uses the seq() function to create a sequence of break points from 5 to 35, with a step of 5.
- This results in bins with ranges 5-10, 10-15, 15-20, 20-25, 25-30, and 30-35. [7]

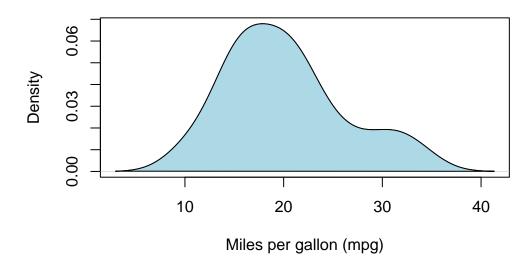

## 10.3.4 Probability Density Function (PDF) plot

- 1. Smoothed approximations of histograms are often represented by density plots, as they assist in offering an estimation of the underlying continuous probability distribution of a given dataset. [7]
- 2. Compared to histograms, these plots often present superior accuracy and aesthetic appeal, and they eliminate the need for arbitrary bin selection. A density plot shares several similarities with a histogram. However, instead of presenting the frequency of individual values, it conveys the probability density of the dataset. [7]

```
# Calculate density
dens <- density(mtcars$mpg)
# Create a density plot
plot(dens,
    main = "Probability Density Function (PDF) of Mileage (mpg)",
    xlab = "Miles per gallon (mpg)",
)
# Add a polygon to fill under the density curve</pre>
```

```
polygon(dens, col = "lightblue", border = "black")
```

# **Probability Density Function (PDF) of Mileage (mpg)**

## 3. Discussion:

- We use the density() function to generate a PDF plot for the mpg column.
- Here, we utilize the plot() function to graph the resulting density object.
- The main argument stipulates the title of the plot, while the xlab argument designates the label for the x-axis.
- Through the polygon() function, we determine the shaded color.
- The final plot displays the probability density of mpg values, using the curve to signify the data distribution. [7]

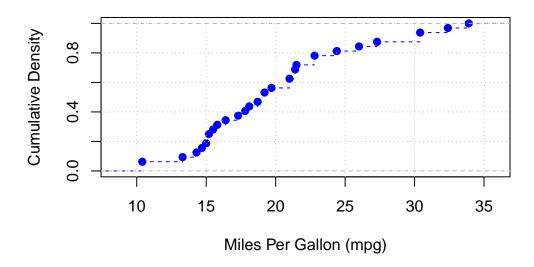

## 10.3.5 Cumulative Distribution Function (CDF) Plot

- 1. CDF plots visualize the fraction of data points that are less than or equal to a specified value on the x-axis [3].
- 2. They facilitate easy representation of the median, percentiles, and spread.
- 3. In R, we can employ the ecdf() function to generate a CDF plot.

```
# Create a CDF plot of mpg column
plot(ecdf(tb$mpg),
```

```
main = "CDF of Miles Per Gallon (mpg)",
    xlab = "Miles Per Gallon (mpg)",
    ylab = "Cumulative Density",
    col = "blue",  # Line color
    lty = 2,
    )
grid(col = "gray", lty = "dotted")  # Add a grid to the plot
```

## **CDF of Miles Per Gallon (mpg)**

- ecdf(tb\$mpg): The function ecdf() computes the empirical cumulative distribution function (CDF) for the mpg column from the tb data frame.
- plot(ecdf(tb\$mpg)): Plots the CDF of the mpg column.
- main, xlab, ylab: Set the title and axis labels.
- col = "blue": Colors the plot line blue; lty = 2: Uses a dashed line.
- grid(col = "gray", lty = "dotted"): Adds a gray, dotted grid to the plot.
- 5. Computing and Inversing CDF Values
- The following code demonstrates how to determine the cumulative distribution function (CDF) value for a given mpg using ecdf() and how to find the mpg value corresponding to a specific CDF with quantile().
- Suppose we want to identify the CDF at mpg = 20, here is how we do it:

```
# Generate the empirical cumulative distribution function
ecdf_func <- ecdf(tb$mpg)

# Derive the CDF for mpg = 20
ecdf_func(20)</pre>
```

## [1] 0.5625

• If we're interested in knowing the mpg value that corresponds to a certain CDF value, the quantile() function comes to our aid. For instance, we can obtain the mpg value associated with a CDF of 0.6 as follows:

```
# Discover the mpg corresponding to CDF = 0.6
quantile(tb$mpg, 0.6)
```

60%

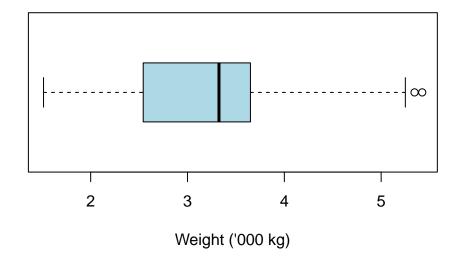

21

## 10.3.6 Box Plot

- 1. Box-and-whisker plots, commonly known as box plots, are crucial graphical instruments for illustrating a distribution's center, spread, and potential outliers [5].
- 2. Here is sample code to generate a boxplot of wt (Weight) of the cars.

```
boxplot(tb$wt,
    main = "Boxplot of Weight (wt)",
    ylab = "",
    xlab = "Weight ('000 kg)",
    col = "lightblue",
    horizontal = TRUE
)
```

## **Boxplot of Weight (wt)**

- 3. The box plot's construction involves the use of an *interquartile range* (IQR) represented by a box, which contains the middle 50% of the dataset, from Q1 to Q3.
- 4. The box's internal line signifies the median, while the "whiskers" reach out to the smallest and largest observations within a distance of 1.5 times the IQR.
- 5. The whiskers extend to the minimum and maximum non-outlier values, or 1.5 times the interquartile range beyond the quartiles, whichever is shorter.
- 6. Any points outside of the whiskers are considered outliers and are plotted individually.
- 7. Discussion:
- The above R code creates a horizontal light blue boxplot for the wt column of the tb data frame, titled "Boxplot of Weight (wt)", with the x-axis labeled "Weight ('000 kg)" and no y-axis label.
- horizontal = TRUE: Renders the boxplot horizontally rather than the default vertical orientation.

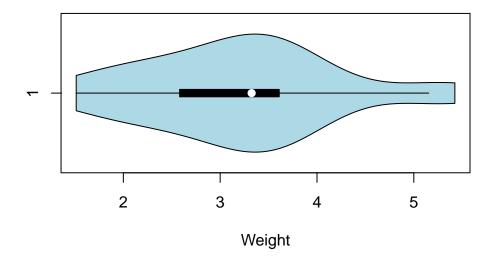

#### 10.3.7 Violin Plot

- 1. Violin plots are a compelling tool to merge the benefits of box plots and kernel density plots and enable us to depict a detailed view of data distribution.
- 2. These plots exhibit the *probability density* at different values, where the plot's *breadth* represents the density or frequency of data points. More extensive areas denote a higher aggregation of data points Akin to a box plot, a violin plot provides a visual display of

the entire data distribution via a kernel density estimate, as opposed to just presenting the quartiles [5].

3. The vioplot() function, part of the vioplot package in R, allows us to create a violin plot.

# **Violin Plot of Weight (wt)**

- In this code, the vioplot() function crafts a violin plot for the wt variable. We use the main argument to assign the plot's title and the xlab argument to designate the axis label.
- The resulting plot unveils the entire wt data distribution, with a kernel density estimate indicating the concentration of data points at different sections.
- The plot also visualizes the boxplot and the median, quartiles, and any outliers present in the data.

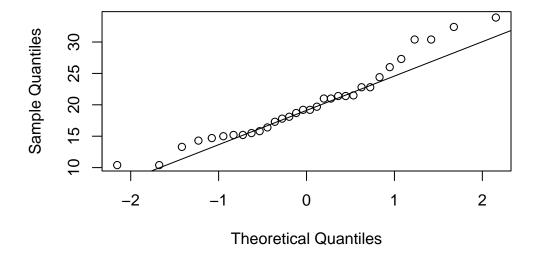

• horizontal = TRUE: Renders the violin plot horizontally rather than the default vertical orientation.

## 10.3.8 Quantile-Quantile (Q-Q) Plot

- 1. Quantile-Quantile plots, commonly referred to as Q-Q plots, are a visual tool we use to check if data follows a particular distribution, like a normal distribution.
- 2. Suppose we order a data column from the smallest to the biggest value, and each data point gets a *score* based on its position. This is what we call a *quantile*. Now, imagine a perfectly normal distribution doing the same thing. In a Q-Q plot, we compare our data's scores to the scores from the ideal normal distribution.
- 3. If our data aligns with the normal distribution, the points in the Q-Q plot will form a straight line. But if our data doesn't follow the normal distribution, the points will stray from the line. This way, the Q-Q plot gives us an intuitive, visual way to decide if our data is normally distributed or not [10].
- 4. In R, we can use the qqnorm() function to create the plot and the qqline() function to add the reference line. If the points lie close to the reference line, it's a good indication that our data is normally distributed.

```
# Generate a Q-Q plot for 'mpg' column
qqnorm(tb$mpg)
# Add a reference line to the plot
qqline(tb$mpg)
```

## Normal Q-Q Plot

5. This approach isn't limited to normal distributions. We can compare our data with other distributions too, which makes Q-Q plots a versatile tool for understanding our data.

# 10.4 Summary of Chapter 12 – Continuous Data (1 of 2)

This section of the book examines continuous univariate data, focusing on single variables in the 'mtcars' dataset using R's dplyr and ggplot packages. We employ R's inherent functions and the 'modeest' package to compute the mean, median, and mode, alongside variability measures like range, variance, and standard deviation.

We use R's 'summary()' and the psych package's 'describe()' functions to create succinct and detailed overviews of our data, providing insights into its central tendency, spread, and distribution shape. These functions can also summarize an entire dataframe or tibble, setting the stage for future analysis.

Visualisations are key to understanding data patterns and distributions. We use bee swarm plots, box plots, violin plots, histograms, and density plots. Bee swarm plots, using the beeswarm() function, show all data points and their distributions. Stem-and-leaf plots, created using the stem() function, provide a quick evaluation of the distribution.

Histograms, constructed with the hist() function, and density plots, using the density() function, display data frequency and smoothed approximations respectively. Cumulative Distribution Function (CDF) plots, via the ecdf() function, show the proportion of data points equal to or less than specific values.

Box plots, made with the boxplot function, highlight the distribution's center, spread, and outliers. Violin plots, via the vioplot() function, merge box plots and kernel density plots to display data density. Lastly, Q-Q plots, created using qqnorm() and qqline(), verify if data follows a normal distribution.

In sum, this chapter presents key R functions and techniques for visualizing continuous univariate data, providing valuable insights into data patterns and distributions.

# 11 11: Continuous Data (2 of 2)

Sep 23, 2023

# 11.1 Exploring Univariate Continuous Data using ggplot2 and ggpubr

This chapter demonstrates the use of the popular ggplot2 and ggpubr packages to further explore univariate, continuous data.

- 1. ggplot2: In the ggplot2 package for instance, the function geom\_boxplot() produces box plots, geom\_violin() creates violin plots, and geom\_histogram() and geom\_density() generate histograms and density plots, respectively. The related ggbeeswarm package can be used for creating bee swarm plots.
- 2. ggpubr: The ggpubr package in R augments ggplot2 by offering tools for creating publication-ready plots. It enables simplified plotting with easy-to-use functions like gghistogram(), ggdensity(), ggboxplot(), ggviolin, and makes it easy to merge multiple plots with ggarrange(), and provides specialized themes for a polished look. Essentially, ggpubr merges ggplot2's extensive customization with the ease of creating visually appealing and informative plots.
- 3. We load the necessary packages, including ggplot2, dplyr and ggthemes packages. The package ggthemes allows us to use a variety of themes.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
library(ggplot2, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(ggpubr, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(rmarkdown, quietly = TRUE, warn.conflicts = FALSE)
library(knitr, quietly = TRUE, warn.conflicts = FALSE)
library(kableExtra, quietly = TRUE, warn.conflicts = FALSE)
library(ggthemes)
```

5. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

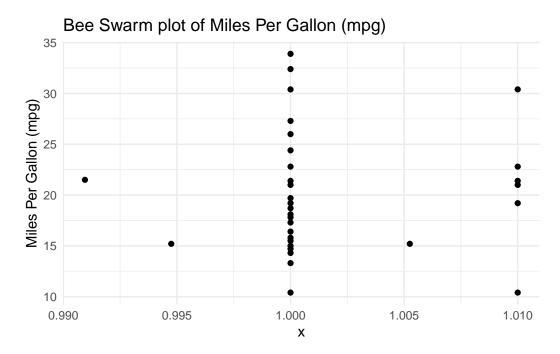

```
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears</pre>
```

- 5. Let's take a closer look at some of the most effective ways of Visualizing Univariate Continuous Data using ggplot2 and related packages, including
- Bee Swarm plots using ggbeeswarm
- Histograms using ggplot2 and ggpubr
- PDF and CDF Density plots using ggplot2 and ggpubr
- Bar plots using ggplot2
- Box plots using ggplot2 and ggpubr
- Violin plots using ggplot2 and ggpubr
- Quantile-Quantile (Q-Q) Plots using ggplot2

Note that it is inconvenient to create Stem-and-Leaf plots using ggplot2.

## 11.1.1 Bee Swarm plot using ggbeeswarm

- 1. The bee swarm plot is an alternative to the box plot, where each point is plotted in a manner that avoids overlap.
- 2. We use the ggbeeswarm package on the mpg column of the tb tibble.

#### 3. Discussion:

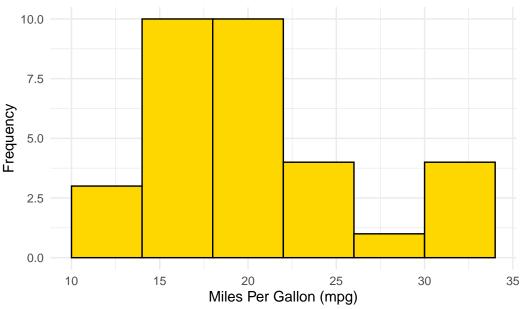

- Initially, we declare our dataset and the aesthetic mappings, defining how variables in the data are visually represented. For the bee swarm plot, we only need a y aesthetic, which is mpg. We set the x aesthetic to 1 as a placeholder, because bee swarm plots require an x aesthetic, but we only have one variable.
- Following that, we append a bee swarm plot using the geom\_beeswarm() function.
- We use the labs() function to label the plot.
- We then adopt a minimalist theme by using theme\_minimal() to give our plot a sleek and simple look.

# 11.2 Histogram using ggplot2

## 11.2.1 Histogram with binwidth

1. The following code creates a histogram using the ggplot2 package. Here, we pre-specify the bin width and the resulting number of bins in the histogram depend on the range of the data.

## Histogram of Mileage, using package 'ggplot2' (setting binwidt

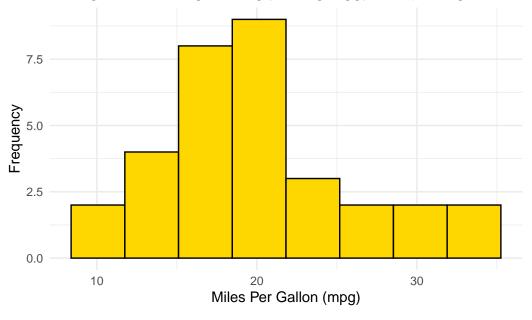

- The code ggplot(tb, aes(x = mpg)) initializes a plot using the tb data frame, mapping the mpg column to the x-axis.
- The histogram is created with geom\_histogram(), using an adjustable binwidth = 4. Given this bin width, the resulting number of bins in the histogram depend on the range of mpg.
- The binwidth argument specifies the width of the bins in the histogram, and we have chosen 4 as an arbitrary width.
- We use fill and color to set the bar colors to be gold with a black border.
- A clean appearance is achieved with theme\_minimal(), and titles and labels are added using labs(). [1]

## 11.2.2 Histogram with bins

3. We could alternately set the number of bins in the histogram, instead of specifying the bin width. In this case, the bin-width gets calculated depending on the range of the data and the specified number of bins.

```
ggplot(tb,
    aes(x = mpg)) +
geom_histogram(bins = 8,
    fill = "gold",
    color = "black") +
theme_minimal() +
labs(title = "Histogram of Mileage, using package `ggplot2` (setting bins = 8)",
    x = "Miles Per Gallon (mpg)", y = "Frequency")
```

## Histogram of Mileage, using package 'ggplot2' (setting bins = 8

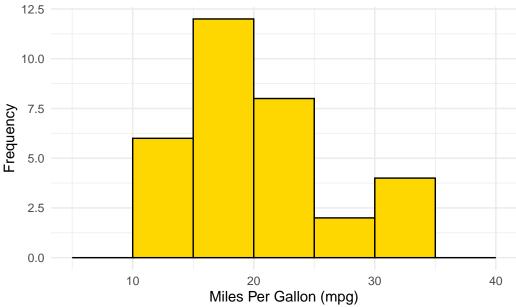

- We instruct R to create a histogram having 8 bins of equal width, by setting bins = 8 ingeom\_histogram()'
- The width of each bin is adjusted by dividing the range of mpg by the number of specified bins.

## 11.2.3 Histogram with bin range

5. Alternately, we can specify custom bin ranges in a histogram. In this this approach, we supply a vector of breakpoints which defines the range of each bin. For example, the following code defines histogram bins with ranges of 5-10, 10-15, 15-20, 20-25, 25-30, 30-35, 35-40, for the mpg variable

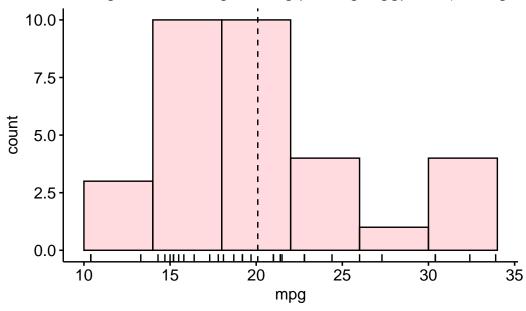

- ggplot(tb, aes(x = mpg)) initializes a ggplot object with the tb data frame and sets the mpg column as the x-axis variable.
- geom\_histogram() adds a histogram layer, in which breaks = seq(5, 40, by = 5) specifies bin edges using a sequence that starts at 5, ends at 40, and increases by 5 units. This results in bins like [5,10), [10,15), and so on.

## 11.2.4 Histogram using ggpubr

7. Recreating a histogram with binwidth of 4, using ggpubr:

```
library(ggpubr)
gghistogram(tb,
    x = "mpg",
    binwidth = 4,
    add = "mean",
    rug = TRUE,
    color = "black" ,
    fill = "lightpink",
    title = "Histogram of Mileage, using package `ggpubr` (setting binwidth = 4) "
```

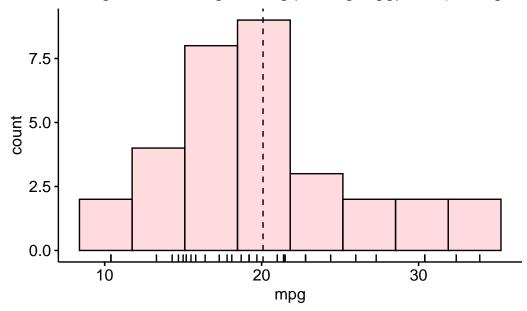

## Histogram of Mileage, using package 'ggpubr' (setting bi

- Here, we're invoking the gghistogram() function from ggpubr to craft a histogram. The data source is specified as tb, and the variable of interest is mpg.
- x = "mpg": This denotes the variable from the we're visualizing.
- binwidth = 4: Each bin in the histogram will span a range of 4 units of mpg.
- add = "mean": Superimposes the mean of mpg on the histogram.

- rug = TRUE: Includes a rug plot at the base, which displays individual data points.
- color = "black": The outline of the bars will be in black.
- fill = "lightpink": Bars in the histogram will be filled with a light pink shade.
- title =: Gives a descriptive title to the histogram.
- In sum, we're visualizing the distribution of the mpg variable from the tb dataset as a light pink histogram, emphasized with black borders, with a bin width of 4 units. We've also marked the mean value and showcased individual data points as a rug plot beneath the histogram.
- 9. Recreating a histogram with 8 bins, using package ggpubr:

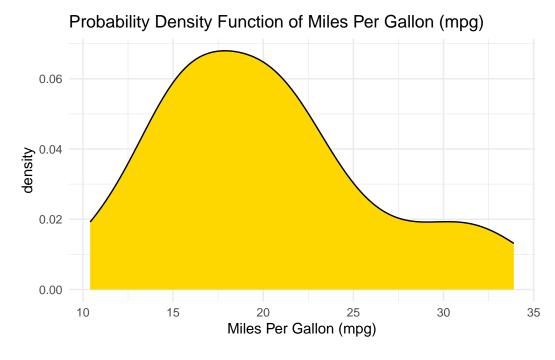

# Histogram of Mileage, using package 'ggpubr' (setting bin

In essence, the difference is that this code visualizes the mpg data from the tb dataset as a histogram with 8 bins, set using bins = 8.

# 11.3 Probability Density Function (PDF) plot using ggplot2

1. Recall that this type of plot shows the distribution of a single variable, and the area under the curve represents the probability of an observation falling within a particular range of values. The following code generates it using ggplot2:

#### 2. Discussion:

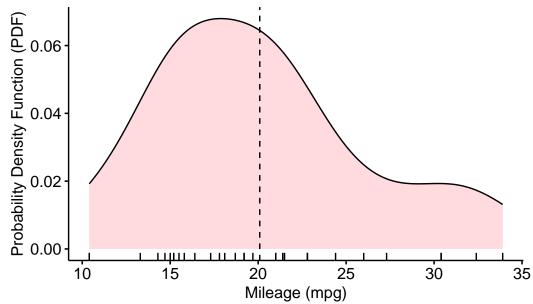

• We designate our data source and the aesthetic mappings using the ggplot() function. The aesthetic mapping for x is mpg.

• Subsequently, we append a density plot to our plot by using the geom\_density() function. We fill the area under the curve by setting fill to "gold".

### 11.3.0.1 PDF using ggpubr

3. The following R code creates a PDF of the mpg variable in the tb dataset, using the ggdensity() function from the ggpubr package.

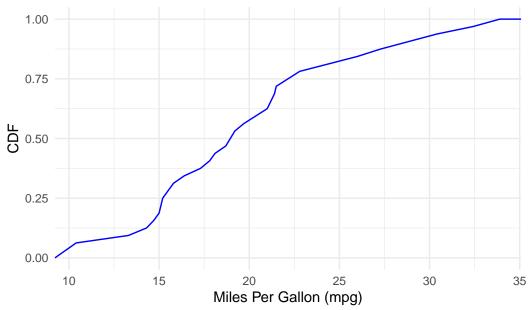

- The ggdensity() function from ggpubr package, is utilized here to visualize a probability density function (PDF) of the mpg variable from the tb dataset.
- x = "mpg": This specifies the column mpg from the tb dataset as the variable we aim to visualize.
- add = "mean": This argument ensures that a line or marker is added to the plot, indicating the mean value of the mpg data.
- rug = TRUE: By setting this to TRUE, a rug plot is added at the bottom, showcasing individual data points.
- color = "black": This defines the border color of the density plot as black.
- fill = "lightpink": This fills the interior of the density plot with a light pink color.
- title = ...: This provides a descriptive title to our plot, aiding in clarity and understanding.

# 11.4 Cumulative Distribution Function (CDF) Plot using ggplot2

1. The following code generates a CDF using ggplot2:

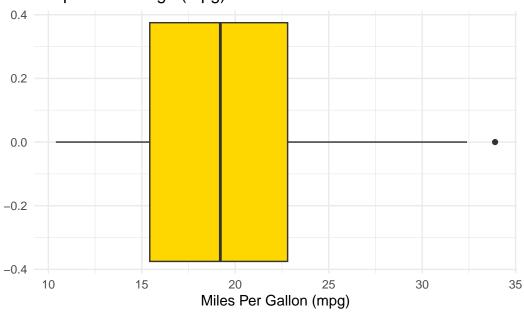

- Here, we're initiating a plot using the ggplot() function, specifying tb as our data source and the mpg column as the variable of interest. '
- We employ the stat\_ecdf() function to represent the empirical cumulative distribution function (CDF) of the mpg data. The geom = "line" argument means the CDF will be displayed as a continuous line, and color = "blue" ensures this line is blue.
- The labs() function is used to define axis labels and a plot title, enhancing readability.
- By invoking theme\_minimal(), we apply a clean and straightforward theme to our plot, which removes extraneous details and emphasizes content.
- To sum up, this code creates a plot depicting the cumulative distribution function (CDF) of the mpg data from the tb dataset.

# 11.5 Boxplots using ggplot2

1. The following code generates a boxplot using ggplot2:

```
ggplot(tb,
    aes(y = mpg)) +
    geom_boxplot(fill = "gold") +
```

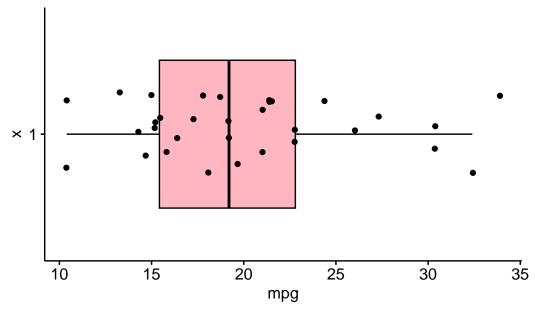

- ggplot(tb, aes(y = mpg)): Initializes a ggplot2 plot using tb with mpg as the y-axis.
- geom\_boxplot(fill = "gold"): Adds a gold-filled boxplot layer.
- theme\_minimal(): Applies a clean, minimalistic theme to the plot.
- coord\_flip(): Flips the plot to display a horizontal boxplot.
- labs(...): Sets the plot title to "Boxplot of Mileage (mpg)" and labels the x-axis as "Miles Per Gallon (mpg)".
- In summary, this code creates a horizontal boxplot of the mpg values from the tb data frame, with the boxes filled in gold color, presented with a minimalistic theme, and labeled appropriately.

### 11.5.1 Boxplot using ggpubr

1. The following code recreates the boxplot using the ggboxplot() function from the ggpubr package.

# Boxplot of Mileage (mpg), using ggpubr::ggboxplot()

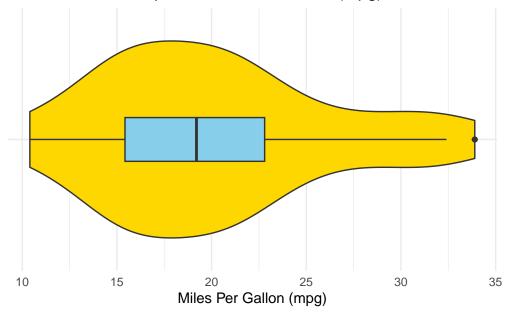

- ggboxplot(tb, y = "mpg"): Creates a boxplot of mpg values from the tb data frame.
- orientation = "horizontal": Sets the boxplot to display horizontally.
- rug = TRUE: Shows a rug plot indicating the density of data points.
- color = "black": Sets the boxplot's border color to black.

- fill = "lightpink": Colors the inside of the boxes light pink.
- add = "jitter": Adds jittered points to the boxplot for clearer data visualization.
- title = ..": Sets the plot's title.

# 11.6 Violin plot using ggplot2

1. The following code generates a violin plot using ggplot2, adding a boxplot to the violin plot:

### Violin Plot with Boxplot of Miles Per Gallon (mpg)

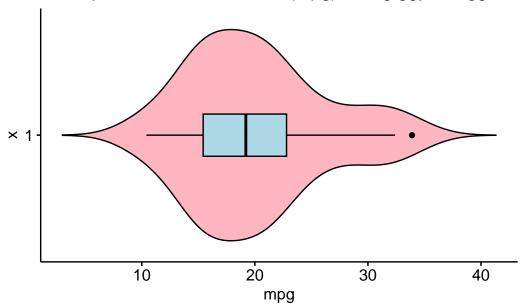

- 2. Discussion:
- geom\_violin() generates the violin plot
- geom\_boxplot() embeds a box plot within it

### 11.6.1 Violin plot using ggpubr

3. The following code recreates the violin plot using the ggviolin() function from the ggpubr package.

# Violin plot of Miles Per Gallon (mpg), using ggpubr::ggviolir

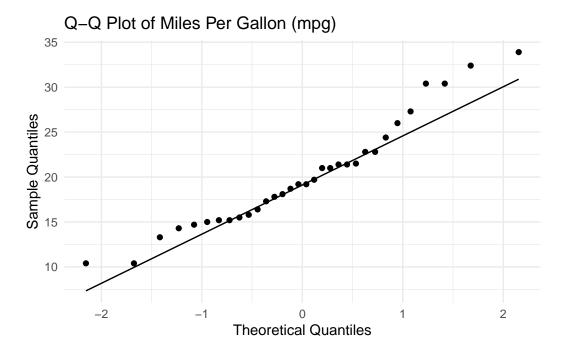

- tb: This refers to the dataset we're using. The dataset should have a variable named "mpg" as we've specified it in the next parameter.
- y = "mpg": This indicates that we want the "mpg" variable (Miles Per Gallon) from the tb dataset to be plotted on the y-axis.

- orientation = "horizontal": This parameter sets the orientation of the violin plot to be horizontal.
- rug = TRUE: This adds a "rug" to the plot, which essentially places small vertical bars (or ticks) at the actual data points along the axis.
- color = "black": The edge color of the violin plot is set to black.
- fill = "lightpink": This sets the main color inside the violin plot to light pink.
- add = "boxplot": This specifies that a boxplot should be added inside the violin plot. A boxplot provides a summary of the distribution, showing the median, quartiles, and potential outliers.
- add.params = list(fill = "lightblue"): This further customizes the added boxplot by setting its fill color to light blue.
- title = "Violin plot of Miles Per Gallon (mpg), using ggpubr::ggviolin()": This sets the title of the plot.
- In summary, the code generates a horizontal violin plot for the "mpg" variable from the tb dataset. The violin plot showcases the distribution of the "mpg" variable, colored in light pink with a light blue boxplot added inside. The rug adds an additional layer of visualization, showing the actual data points along the axis.

# 11.7 Quantile-Quantile (Q-Q) Plots using ggplot2

1. Recall that a Q-Q plot is a graphical method for comparing two probability distributions by plotting their quantiles against each other. The following code generates a Quantile-Quantile (Q-Q) plot using ggplot2,

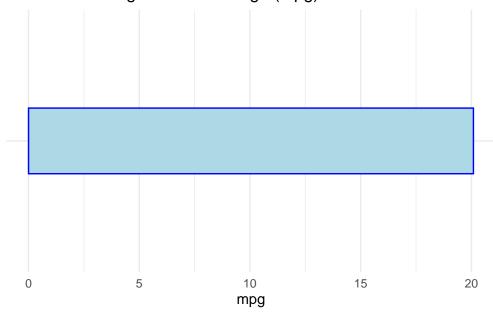

- ggplot(tb, aes(sample = mpg)): Here, we initiate a ggplot graphic using the tb dataset and set the aesthetic (aes) to the "mpg" variable. In the context of the stat\_qq() function (which we'll come to shortly), the sample aesthetic specifies the data variable for which we want to create the Q-Q plot.
- stat\_qq(): This function adds the Q-Q plot points to the graphic. The x-axis of this plot represents the quantiles from a theoretical distribution (often the standard normal distribution), and the y-axis represents the quantiles from our sample data ("mpg").
- stat\_qq\_line(): This function adds a reference line to the Q-Q plot, which represents the expected line if the sample comes from the specified distribution (again, often the standard normal distribution). If our data points lie roughly on this line, it suggests that the data follows the theoretical distribution.
- In summary, this code produces a Q-Q plot for the "mpg" variable from the tb dataset. The plot compares the quantiles of "mpg" against the quantiles of a theoretical distribution, often the standard normal distribution.

# 11.8 Bar Plot visualizing the Mean and SD using ggplot2

1. We can create a Bar Plot to visualize the mean of a continuous variable.

### Bar Plot showing Mean of Mileage (mpg)

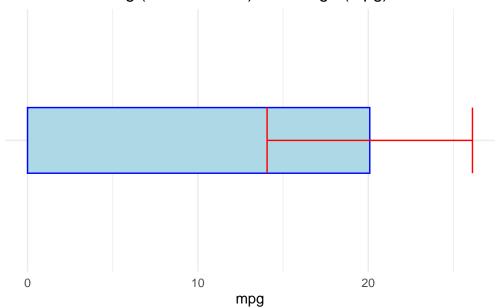

2. We can extend this to create a Bar Plot with Error Bars to visualization the Mean and the Standard Deviation of a continuous variable.

```
# Create a summary data frame
mpgSummary <- tb %>%
```

```
summarise(
   MeanMpg = mean(mpg, na.rm = TRUE),
   SDMpg = sd(mpg, na.rm = TRUE)
# Create a box plot visualizing the mean and error bars visualizing the SD
ggplot(mpgSummary,
      aes(y = "",
          x = MeanMpg)) +
 geom_bar(stat = "identity",
          fill = "lightblue", color = "blue", width = 0.3
 geom_errorbar(aes(xmin = MeanMpg - SDMpg,
                    xmax = MeanMpg + SDMpg),
                color = "red", width = 0.3
                ) +
 labs(x = "mpg", y = "",
      title = "Bar Plot showing (Mean +/- SD) of Mileage (mpg)") +
 theme_minimal()
```

## Bar Plot showing (Mean +/- SD) of Mileage (mpg)

#### 3. Discussion

Summary Data Frame (mpgSummary) Creation:

• mpgSummary <- tb %>% summarise(...): This line is initializing the creation of

- mpgSummary data frame using the data in tb (which is assumed to contain the mtcars dataset) and the summarise function from the dplyr package.
- MeanMpg = mean(mpg, na.rm = TRUE): Calculates the mean of the mpg column, ignoring any NA values, and creates a new column MeanMpg in mpgSummary to store this value.
- SDMpg = sd(mpg, na.rm = TRUE): Calculates the standard deviation of the mpg column, ignoring any NA values, and creates a new column SDMpg in mpgSummary to store this value.

#### Bar Plot with Error Bars Creation:

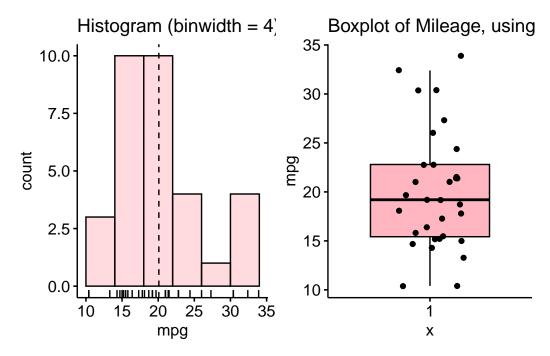

- ggplot(mpgSummary, aes(y = "", x = MeanMpg)) +: Initializes the creation of a ggplot object using the mpgSummary data frame and sets the aesthetic mappings where x is mapped to MeanMpg and y is set to an empty string.
- geom\_bar(stat = "identity", fill = "lightblue", color = "blue", width = 0.3): Adds a bar geometry to represent the mean mpg (MeanMpg). The bar is colored light blue with a blue border and has a width of 0.3.
- geom\_errorbar(aes(xmin = MeanMpg SDMpg, xmax = MeanMpg + SDMpg), color = "red", width = 0.3): Adds error bars to represent the variability of mpg. The error bars extend from MeanMpg SDMpg to MeanMpg + SDMpg and are colored red with a width of 0.3.
- labs(x = "mpg", y = "", title = "Bar Plot showing (Mean +/- SD) of Mileage (mpg)"): Adds labels to the plot, with "mpg" as the x-axis label, no y-axis label, and a title indicating that the plot shows the mean and standard deviation of mileage.
- theme\_minimal(): Applies a minimal theme to the plot for a clean and uncluttered appearance.
- The end result of executing this code is a bar plot visualizing the mean of the mpg column and error bars representing one standard deviation above and below the mean, giving a sense of the variability of the miles per gallon in the mtcars dataset.

# 11.9 Combining Plots using ggarrange()

1. The following code showcases two plots side-by-side.

```
library(ggplot2)
library(ggpubr)
PlotHist <- gghistogram(tb,</pre>
```

```
x = "mpg",
            binwidth = 4,
            add = "mean",
            rug = TRUE,
            color = "black" ,
            fill = "lightpink",
            title = "Histogram (binwidth = 4) "
)
PlotBox <- ggboxplot(tb,</pre>
            y = "mpg",
            rug = TRUE,
            color = "black" ,
            fill = "lightpink",
            add = "jitter",
            title = "Boxplot of Mileage, using ggpubr"
)
# Combine the plots using ggarrange()
combined_plot <- ggarrange(PlotHist, PlotBox, ncol = 2)</pre>
# Display the combined plot
print(combined_plot)
```

- We create a histogram and a boxplot using the same code discussed above.
- ggarrange(PlotHist, PlotBox, ncol = 2): This code helps us combine multiple plots into one. Here, PlotHist (the histogram) and PlotBox (the boxplot) are arranged side by side, as indicated by ncol = 2.
- In essence, this code facilitates a side-by-side comparison of the distribution of the mpg variable from the tb dataset using two different types of visualizations: a histogram and a boxplot.

# 11.10 Summary of Chapter 13 - Continuous Data (2 of 2)

In this chapter, we explore how to visualize univariate continuous data using the ggplot2 package in R. We use the mtcars data set, converting it to a tibble called tb for easier manipulation.

The visualization methods we cover include histograms, density plots (Probability Density Function and Cumulative Density Function), box plots, bee swarm plots, violin plots, and Q-Q plots. These are created using functions like geom\_histogram(), geom\_density(), geom\_boxplot(), geom\_beeswarm(), geom\_violin(), stat\_qq(), and stat\_qq\_line().

For the histogram, we can adjust bin width, color, and number of bins, or define custom bin ranges. The density plots provide a visual representation of the distribution of a variable, and we can color the area under the curve. To create the CDF plot, we first arrange our data and calculate the cumulative distribution, which is plotted as a line graph. For the violin plot, we show how to add a box plot within the violin for additional information. Finally, we explore Q-Q plots, which compare the quantiles of our data to a theoretical distribution, useful for assessing if the data follows a certain theoretical distribution.

# 12 12: Categorical x Continuous data (1 of 2)

Aug 13, 2023

- 1. THIS CHAPTER explores Categorical x Continuous data. It explains how to summarize and visualize bivariate continuous data across categories. Here, we delve into the intersection of continuous data and categorical variables, examining how the former can be split, summarized, and compared across different levels of one or more categorical variables.
- 2. We bring to light methods for generating statistics per group and data manipulation techniques. This includes processes like grouping, filtering, and summarizing continuous data, contingent on categorical variables. We visualize such data by creating juxtaposed box plots, segmented histograms, and density plots that reveal the distribution of continuous data across varied categories.
- 3. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
library(knitr) # For formatting tables
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears
# Directly access the data columns of tb, without tb$mpg
attach(tb)</pre>
```

# 12.1 Summarizing Continuous Data

### 12.1.1 Across one Category

• We review the use of the inbuilt functions (i) aggregate(); (ii) tapply(); and the function (iii) describeBy() from package pysch, to summarize continuous data split across a category.

### 1. Using aggregate()

• We use the aggregate() function to investigate the bivariate relationship between mileage (mpg) and number of cylinders (cyl). The following code displays a summary table showing the average mileage of the cars broken down by number of cylinders (cyl = 4, 6, 8) using aggregate().

Table 12.1: Mean of Mileage (mpg) by Cylinder (cyl=4,6,8)

Cylinders	Mean_mpg
4	26.66
6	19.74
8	15.10

#### 2. Discussion:

- The first argument in aggregate() is the data vector tb\$mpg.
- The second argument, by, denotes a list of variables to group by. Here, we have supplied tb\$cyl, since we wish to partition our data based on the unique values of cyl.
- The third argument, FUN, is the function we want to apply to each subset of data. We are using mean here, calculating the average mpg for each unique cyl value. We can alternately aggregate based on a variety of statistical functions including sum, median, min, max, sd, var, length, IQR.
- The output of aggregate() is saved in a new tibble named agg. We utilize the names() function to rename the columns and display agg. [1]

### 3. Using tapply()

• The tapply() function is another convenient tool to apply a function to subsets of a vector, grouped by some factors.

```
A1 <- tapply(tb$mpg,
tb$cyl,
mean)
```

4 6 8 26.66364 19.74286 15.10000

#### 4. Discussion:

- In this code, tapply(tb\$mpg, tb\$cyl, mean) calculates the average miles per gallon (mpg) for each unique number of cylinders (cyl) within the tb tibble.
- tb\$mpg represents the vector to which we want to apply the function.
- tb\$cyl serves as our grouping factor.
- mean is the function that we're applying to each subset of our data.
- The result will be a vector where each element is the average mpg for a unique number of cylinders (cyl), as determined by the unique values of tb\$cyl. [1]
- 5. Using describeBy() from package psych
- The describeBy() function, part of the psych package, can be used to compute descriptive statistics of a numeric variable, broken down by levels of a grouping variable.

```
library(psych)
A2 <- describeBy(mpg, cyl)
print(A2)</pre>
```

```
Descriptive statistics by group group: 4
```

vars n mean sd median trimmed mad min max range skew kurtosis se X1 1 11 26.66 4.51 26 26.44 6.52 21.4 33.9 12.5 0.26 -1.65 1.36

group: 6

vars n mean sd median trimmed mad min max range skew kurtosis se X1 1 7 19.74 1.45 19.7 19.74 1.93 17.8 21.4 3.6 -0.16 -1.91 0.55

-----

```
group: 8

vars n mean sd median trimmed mad min max range skew kurtosis se
X1 1 14 15.1 2.56 15.2 15.15 1.56 10.4 19.2 8.8 -0.36 -0.57 0.68
```

#### 6. Discussion:

- describeBy(mpg, cyl) computes descriptive statistics of miles per gallon mpg variable, broken down by the unique values in the number of cylinders (cyl).
- It calculates statistics such as the mean, sd, median, for mpg, separately for each unique number of cylinders (cyl). [2]

### 12.1.2 Across two Categories

- We extend the above discussion and study how to summarize continuous data split across **two** categories.
- We review the use of the inbuilt functions (i) aggregate() and the function (ii) describeBy() from package pysch. While the tapply() function can theoretically be employed for this task, the resulting code tends to be long and lacks efficiency. Therefore, we opt to exclude it from practical use.

#### 1. Using aggregate()

• Distribution of Mileage (mpg) by Cylinders (cyl =  $\{4,6,8\}$ ) and Transmisson Type (am =  $\{0,1\}$ )

Table 12.2: Mean of Mileage (mpg) by Cylinders (cyl=4,6,8) and Transmission (am=0,1)

Cylinders	Transmission	Mean_mpg
4	0	22.90
6	0	19.12
8	0	15.05
4	1	28.08
6	1	20.57
8	1	15.40

- In our code, the first argument of aggregate() is tb\$mpg, indicating that we want to perform computations on the mpg variable.
- The by argument is a list of variables by which we want to group our data, specified as list(tb\$cyl, tb\$am). This means that separate computations are done for each unique combination of cyl and am.
- The FUN argument indicates the function to be applied to each subset of our data. Here, we use mean, meaning that we compute the mean mpg for each group.
- 3. Using aggregate() for multiple continuous variables: Consider this extension of the above code for calculating the mean of three variables mpg, wt, and hp, grouped by both am and cyl variables:
- Distribution of Mileage (mpg), Weight (wt), Horsepower (hp) by Cylinders (cyl =  $\{4,6,8\}$ ) and Transmisson Type (am =  $\{0,1\}$ )

Table 12.3: Mean of Mileage (mpg), Weight (wt), Horsepower (hp) by Transmission (am=0,1) and Cylinders (cyl=4,6,8)

Transmission	Cylinders	Mean_mpg	Mean_wt	Mean_hp
0	4	22.90	2.94	84.67
1	4	28.08	2.04	81.88
0	6	19.12	3.39	115.25
1	6	20.57	2.76	131.67
0	8	15.05	4.10	194.17
1	8	15.40	3.37	299.50

#### 4. Discussion:

• In this code, the aggregate() function takes a list of the three variables as its first argument, indicating that the mean should be calculated for each of these variables

separately within each combination of am and cyl.

- The sequence of the categorizing variables also varies initially, the data is grouped by cyl, followed by a subdivision based on am.
- 5. Using aggregate() with multiple functions: Consider an extension of the above code for calculating the mean and the SD of mpg, grouped by both am and cyl factor variables:
- Distribution of Mileage (mpg), by Cylinders (cyl =  $\{4,6,8\}$ ) and Transmission Type (am =  $\{0,1\}$ )

```
agg_mean <- aggregate(tb$mpg,
                      by = list(tb$cyl, tb$am),
                      FUN = mean)
agg_sd <- aggregate(tb$mpg,
                    by = list(tb$cyl, tb$am),
                    FUN = sd)
agg_median <- aggregate(tb$mpg,
                        by = list(tb$cyl, tb$am),
                        FUN = median)
# Merge them together, two data frames at a time
B2 <- merge(agg_mean, agg_sd,
            by = c("Group.1", "Group.2"))
B2 <- merge(B2, agg_median,
            by = c("Group.1", "Group.2"))
# Rename columns for clarity
names(B2) <- c("Cylinders", "Transmission", "Mean mpg", "SD mpg", "Median mpg")</pre>
kable(B2,
      digits=2, caption = "Mean, SD, Median of Mileage (mpg) by Cylinders (cyl=4,6,8) and
```

Table 12.4: Mean, SD, Median of Mileage (mpg) by Cylinders (cyl=4,6,8) and Transmission (am=0,1)

Cylinders	Transmission	Mean_mpg	$SD_mpg$	Median_mpg
4	0	22.90	1.45	22.80
4	1	28.08	4.48	28.85
6	0	19.12	1.63	18.65
6	1	20.57	0.75	21.00
8	0	15.05	2.77	15.20
8	1	15.40	0.57	15.40

- We analyze our dataset to comprehend the relationships between vehicle miles per gallon (mpg), number of cylinders (cyl), and type of transmission (am).
- Initially, we computed the mean, standard deviation, and median of mpg for every unique combination of cyl and am.
- After individual computations, we combined these results into a single, comprehensive data frame called merged\_data. This structured dataset now clearly presents the average, variability, and median of fuel efficiency segmented by cylinder count and transmission type.

### 7. Using describeBy() from package psych

• The describeBy() function, part of the psych package, can be used to compute descriptive statistics of continuous variable, broken down by levels of a two categorical variables. Consider the following code:

```
Descriptive statistics by group
: 0
: 4
    vars n mean
                    sd median trimmed mad
                                             min
                                                    max range
                                                               skew kurtosis
       1 3 22.90
                 1.45
                        22.80
                                22.90 1.93 21.50 24.40
                                                         2.90
                                                               0.07
                                                                       -2.33

#### 7. Discussion:

- We specify a subset of the dataframe tb that includes only the columns of interest mpg,
   wt, and hp and save it into a variable tb\_columns.
- Next, we create a list, tb\_factors, that contains the factors am and cyl.
- After that, we call the describeBy() function from the psych package. This function calculates descriptive statistics for each combination of levels of the factors am and cyl and for each of the continuous variables mpg, wt, and hp.

# 12.2 Visualizing Continuous Data

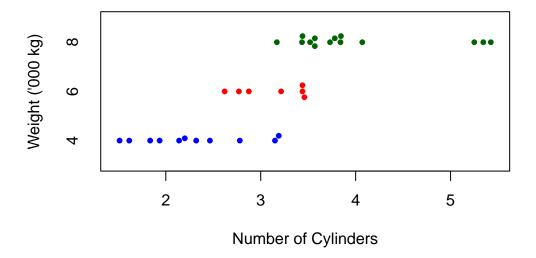

Let's take a closer look at some of the most effective ways of visualizing univariate continuous data, including

- (i) Bee Swarm plots;
- (ii) Stem-and-Leaf plots;
- (iii) Histograms;
- (iv) PDF and CDF Density plots;
- (v) Box plots;
- (vi) Violin plots;
- (vii) Q-Q plots.

#### 12.2.1 Bee Swarm Plot

- 1. We extend a Bee Swarm plot of a *one-dimensional scatter plot* for a continuous variable, split by a categorical variable. [6]
- 2. Consider the following code, which generates a beeswarm plot displaying vehicle weights (wt) segmented by their number of cylinders (cyl):

# Bee Swarm Plot of Weight (wt) by Cylinders (cyl=4,6,8)

- **Data**: We use tbwt tbcyl to specify that we want a beeswarm plot for Weight (wt), split by no of cylinders (cyl),
- Title: It is labeled "Bee Swarm Plot of Weight (wt) by Number of Cylinders".

- Axes Labels: The x-axis shows "Number of Cylinders", while the y-axis denotes "Weight ('000 kg)".
- Data Points: Using pch=16, data points appear as solid circles.
- Size of Points: With cex=0.8, these circles are slightly smaller than default.
- Colors: The col parameter assigns colors ("blue", "red", and "dark green") based on cylinder counts.
- Orientation: Set as horizontal with horizontal=TRUE.
- To summarize, this visual distinguishes vehicle weights across cylinder counts and highlights data point densities for each group.

### 12.2.2 Stem-and-Leaf Plot across one Category

- 1. Suppose we wanted to visualize the distribution of a continuous variable across different levels of a categorical variable, using stem-and-leaf plots.
- 2. To illustrate, let us display vehicle weights (wt) separately for each transmission type (am) using stem-and-leaf plots.

The decimal point is at the |

- 2 I 5
- 3 | 22244445567888
- 4 | 1
- 5 | 334

```
The decimal point is at the |

1   | 5689
2   | 123
2   | 6889
3   | 2
3   | 6

$`0`
NULL

$`1`
NULL
```

- Column Selection: The code extracts the wt (weight) and am (transmission type) columns from tb and saves them in tb3.
- Data Splitting: It then divides tb3 into subsets based on am values, resulting in separate groups for each transmission type.
- Visualization: Using lapply(), the code generates stem-and-leaf plots for the wt values in each subset, showcasing weight distributions for different transmission types. In this context, it shows the distribution of vehicle weights for each transmission type (automatic and manual).

### 12.2.3 Histograms across one Category

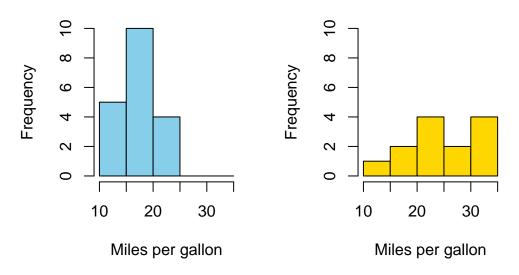

1. Visualizing histograms of car mileage (mpg) broken down by transmission (am=0,1)

```
split_data <- split(tb$mpg, tb$am) # Split the data by 'am' variable
par(mfrow = c(1, 2)) # Create a 1-row 2-column layout
color_vector <- c("skyblue", "gold") # Define the color vector

# Create a histogram for subset with am = 0
hist(split_data[[1]],
    main = "Histogram of mpg (am = 0)",
    breaks = seq(10, 35, by = 5), # This creates bins with ranges 10-15, 15-20, etc.
    xlab = "Miles per gallon",
    col = color_vector[1], # Use the color vector,
    border = "black",
    ylim = c(0, 10))</pre>
```

```
# Create a histogram for subset with am = 1
hist(split_data[[2]],
    main = "Histogram of mpg (am = 1)",
    breaks = seq(10, 35, by = 5), # This creates bins with ranges 10-15, 15-20, etc.
    xlab = "Miles per gallon",
    col = color_vector[2], # Use the color vector,
    border = "black",
    ylim = c(0, 10))
```

# Histogram of mpg (am = 0 Histogram of mpg (am = 1

In Appendix A1, we have alternative code written using a for loop

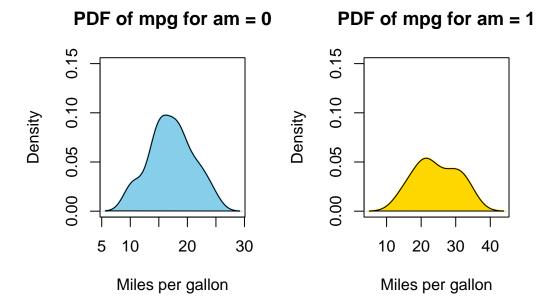

- We aim to visualize the distribution of the mpg values from the tb dataset based on the am variable, which can be either 0 or 1.
- Data Splitting: We segregate mpg values into two subsets using the split function, depending on the am values. In R, the double brackets [[ ]] are used to access the elements of a list or a specific column of a data frame. split\_data[[1]] accesses the first element of the list split\_data.
- Layout Setting: The par function is configured to display two plots side by side in a single row and two columns format.
- 3. Color Vector: We introduce a color\_vector to assign distinct colors to each histogram for differentiation.

4. Histogram: Two histograms are generated, one for each am value (0 and 1). These histograms use various parameters like title, x-axis label, color, and y-axis limits to provide a clear representation of the data's distribution. [4]

### 12.2.4 Probability Density Function (PDF) across one Category

1. Visualizing Probability Density Functions (PDF) of car mileage (mpg) broken down by transmission (am=0,1)

```
split_data <- split(tb$mpg, tb$am) # Split 'mpg' data by 'am' values
par(mfrow = c(1, 2)) # Set layout for 2 plots side by side
color_vector <- c("skyblue", "gold") # Define colors for the plots</pre>
# Calculate density for am = 0 and plot it
dens_0 <- density(split_data[[1]])</pre>
plot(dens_0,
     main = "PDF of mpg for am = 0",
     xlab = "Miles per gallon",
     col = color_vector[1],
     border = "black",
     ylim = c(0, 0.15),
     lwd = 2) # Plot density curve for am = 0
polygon(dens_0, col = color_vector[1], border = "black") # Fill under the curve
# Calculate density for am = 1 and plot it
dens_1 <- density(split_data[[2]])</pre>
plot(dens 1,
     main = "PDF of mpg for am = 1",
     xlab = "Miles per gallon",
     col = color_vector[2],
     border = "black",
     ylim = c(0, 0.15),
     lwd = 2) # Plot density curve for am = 1
polygon(dens_1, col = color_vector[2], border = "black") # Fill under the curve
```

In Appendix A2, we have alternative code written using a for loop

- dens\_0 <- density(split\_data[[1]]) calculates the density values for the subset where am is 0.
- The subsequent plot function visualizes the density curve, setting various parameters like the title, x-axis label, color, and line width.
- The polygon function fills the area under the density curve with the specified color, giving a shaded appearance to the plot.
- The process is repeated for the subset where am is 1. The code calculates the density, plots it, and then uses the polygon function to shade the area under the curve.

In Appendix A3, we demonstrate how to draw overlapping PDFs on the same plot, using base R functions.

### 12.2.5 Cumulative Density Function (CDF) across one Category

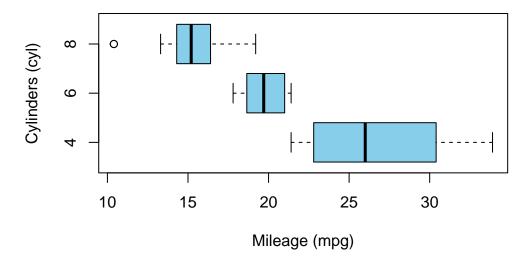

In Appendix A4, we demonstrate how to draw a CDF, using base R functions

### 12.2.6 Box Plots across one Category

1. Visualizing Median using Box Plot – median weight of the cars broken down by cylinders (cyl=4,6,8)

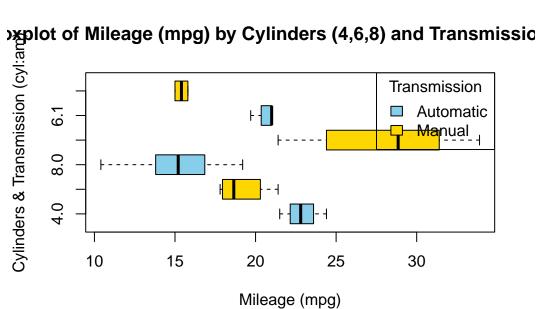

```
boxplot(mpg~cyl,
    main = "Boxplot of Mileage (mpg) by Cylinders (cyl=4,6,8)",
    xlab = "Mileage (mpg)",
    ylab = "Cylinders (cyl)",
    col = c("skyblue"),
    horizontal = TRUE
    )
```

# Boxplot of Mileage (mpg) by Cylinders (cyl=4,6,8)

- This code creates a visual representation of the distribution of miles per gallon (mpg) based on the number of cylinders (cyl), using the boxplot function from the base graphics package in R. down:
- Data Input: The formula mpg ~ cyl instructs R to create separate boxplots for each unique value of cyl, with each boxplot representing the distribution of mpg values for that particular cylinder count.
- Title Configuration: main specifies the title of the plot as "Boxplot of Miles Per Gallon (mpg) by Cylinders."

- Axis Labels: The labels for the x-axis and y-axis are set using xlab and ylab, respectively. Here, xlab labels the mileage (or mpg), while ylab labels the number of cylinders (cyl).
- Color Choice: The col argument is set to "skyblue," which colors the body of the boxplots in a light blue shade.
- Orientation: By setting horizontal to TRUE, the boxplots are displayed in a horizontal orientation rather than the default vertical orientation.
- In essence, we're visualizing the variations in car mileage based on the number of cylinders using horizontal boxplots. This type of visualization helps in understanding the central tendency, spread, and potential outliers of mileage for different cylinder counts.
- 3. Visualizing Median using Box Plot median weight of the cars broken down by cylinders (cyl=4,6,8) and Transmission (am=0,1)

- This R code presents a horizontal boxplot showcasing the distribution of mileage (mpg) based on the interaction between the number of car cylinders (cyl) and the type of transmission (am).
- Boxplot Creation: The boxplot function is used to generate the visualization. With the formula mpg ~ cyl \* am, we plot the distribution of mpg for every combination of cyl and am.
- Color Configuration: The col argument specifies the colors for the boxplots. We've opted for "skyblue" and "gold" for differentiation. Depending on the order of factor levels in your data, one color typically represents one level of am (e.g., automatic) and the other color represents the second level (e.g., manual).
- Orientation: The horizontal argument, set to TRUE, orients the boxplots horizontally.
- Legend Addition: Following the boxplot, we add a legend using the legend function. Placed at the "topright" position, this legend differentiates between "Automatic" and "Manual" transmissions using the designated colors.
- In essence, our code generates a detailed visualization that elucidates the mileage distribution for various combinations of cylinder counts and transmission types in cars.

#### 12.2.7 Means Plot across one Category

Visualizing Means – mean plot showing the average weight of the cars, broken down by transmission (am = 0 or 1)

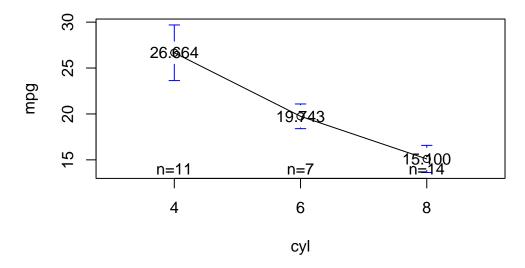

```
library(gplots)
```

Attaching package: 'gplots'

The following object is masked from 'package:stats':

lowess

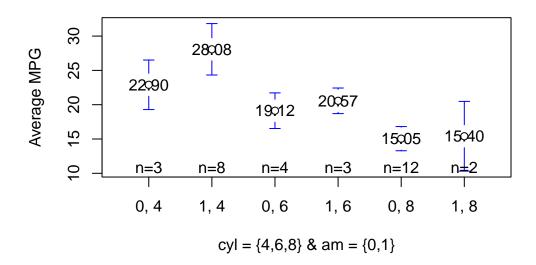

# Mean(mpg) by $cyl = \{4,6,8\}$

### 12.2.8 Means Plot across two Categories

We show a mean plot showing the mean weight of the cars broken down by Transmission Type (am = 0 or 1) & cylinders (cyl = 4,6,8).

### Mean (mpg) by cyl = $\{4,6,8\}$ & am = $\{0,1\}$

### 12.4 Appendix

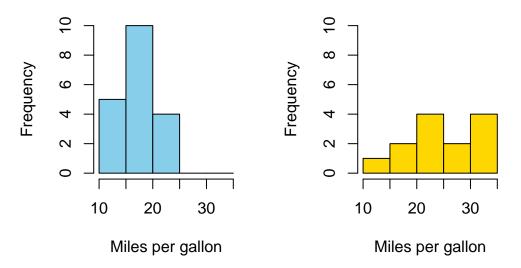

#### 12.4.0.1 Appendix A1

Visualizing histograms of car mileage (mpg) broken down by transmission (am=0,1)

Code written using a for loop

```
# Split the data by 'am' variable
split_data <- split(tb$mpg, tb$am)</pre>
# Create a 1-row 2-column layout
par(mfrow = c(1, 2))
# Define the color vector
color_vector <- c("skyblue", "gold")</pre>
# Create a histogram for each subset
for (i in 1:length(split_data)) {
  hist(split_data[[i]],
       main = paste("Histogram of mpg for am =", i - 1),
       breaks = seq(10, 35, by = 5), # This creates bins with ranges 10-15, 15-20, etc.
       xlab = "Miles per gallon",
       col = color_vector[i], # Use the color vector,
       border = "black",
       ylim = c(0, 10))
}
```

# Histogram of mpg for am = Histogram of mpg for am =

#### 12.4.0.2 Appendix A2

Visualizing Probability Density Function (PDF) of car milegage (mpg) broken down by transmission (am=0,1), using for loop

```
# Split the data by 'am' variable
split_data <- split(tb$mpg, tb$am)

# Create a 1-row 2-column layout
par(mfrow = c(1, 2))

# Define the color vector
color_vector <- c("skyblue", "gold")

# Create a density plot for each subset
for (i in 1:length(split_data)) {
    # Calculate density
    dens <- density(split_data[[i]])

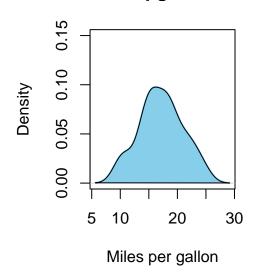

# Plot density
plot(dens,
    main = paste("PDF of mpg for am =", i - 1),
    xlab = "Miles per gallon",
    col = color_vector[i],</pre>
```

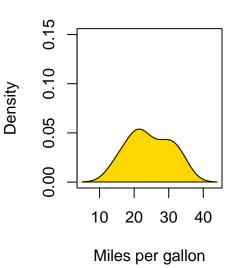

```
border = "black",
    ylim = c(0, 0.15), # Adjust this value if necessary
    lwd = 2) # line width

# Add a polygon to fill under the density curve
    polygon(dens, col = color_vector[i], border = "black")
}
```

# PDF of mpg for am = 0

# PDF of mpg for am = 1

#### 12.4.0.3 Appendix A3

Visualizing Probability Density Function (PDF) of car milegage (mpg) broken down by transmission (am=0,1), overlapping PDFs on the same plot

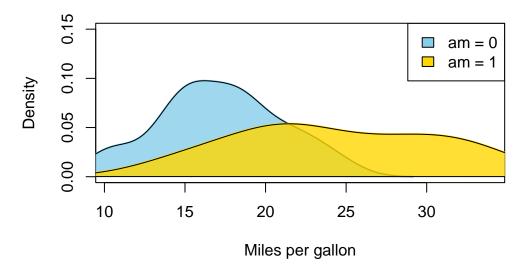

```
# Split the data by 'am' variable
split_data <- split(tb$mpg, tb$am)

# Define the color vector
color_vector <- c("skyblue", "gold")

# Define the legend labels
legend_labels <- c("am = 0", "am = 1")

# Create a density plot for each subset
# Start with an empty plot with ranges accommodating both data sets</pre>
```

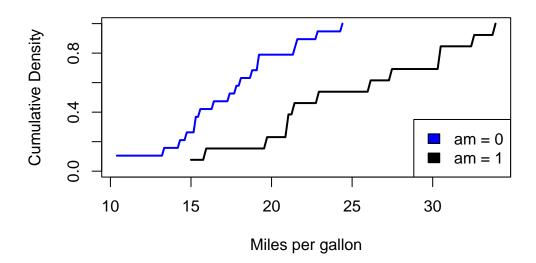

# PDFs of Mileage (mpg) for automatic, manual transmissions

#### 12.4.0.4 Appendix A4

```
# Split the data by 'am' variable
split_data <- split(tb$mpg, tb$am)</pre>
# Define the color vector
color_vector <- c("blue", "black")</pre>
# Define the legend labels
legend_labels <- c("am = 0", "am = 1")
# Create a cumulative density plot for each subset
# Start with an empty plot with ranges accommodating both data sets
plot(0, 0, xlim = range(mtcars$mpg), ylim = c(0, 1), type = "n",
     xlab = "Miles per gallon", ylab = "Cumulative Density",
     main = "CDFs of Mileage (mpg) for automatic, manual transmissions (am)")
for (i in 1:length(split_data)) {
  # Calculate empirical cumulative density function
  ecdf_func <- ecdf(split_data[[i]])</pre>
  # Add CDF plot using curve function
  curve(ecdf_func(x),
        from = min(split_data[[i]]), to = max(split_data[[i]]),
        col = color_vector[i],
        add = TRUE,
        lwd = 2) # line width
# Add legend to the plot
legend("bottomright", legend = legend_labels, fill = color_vector, border = "black")
```

# **CDFs** of Mileage (mpg) for automatic, manual transmissions

# 13 13: Categorical x Continuous data (2 of 2)

Sep 23, 2023

- 1. This chapter explores Categorical x Continuous data using the dplyr and ggplot2 packages.
- 2. **Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
library(knitr) # For formatting tables
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears
# Directly access the data columns of tb, without tb$mpg
attach(tb)</pre>
```

# 13.1 Visualizing Continuous Data using ggplot2

Let's take a closer look at some of the most effective ways of visualizing continuous data, across one Category, **using ggplot2**, including

- (i) Bee Swarm plots, using ggplot2;
- (ii) Histograms, using ggplot2;
- (iii) PDF and CDF Density plots, using ggplot2;
- (iv) Box plots, using ggplot2;

(v) Violin plots, using ggplot2;

#### 13.1.1 Bee Swarm Plot across one Category using ggbeeswarm

• Visualizing Median using Box Plot – median weight of the cars broken down by cylinders (cyl=4,6,8)

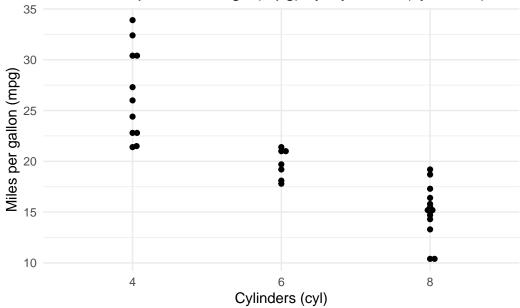

```
library(ggplot2)

Attaching package: 'ggplot2'

The following object is masked from 'tb':
    mpg

library(ggbeeswarm)
# Create the beeswarm plot
ggplot(mtcars,
    aes(x = factor(cyl),
        y = mpg)) +
geom_beeswarm() +
labs(title = "Bee Swarm plot of Mileage (mpg) by Cylinders (cyl=4,6,8)",
    x = "Cylinders (cyl)",
    y = "Miles per gallon (mpg)") +
theme_minimal()
```

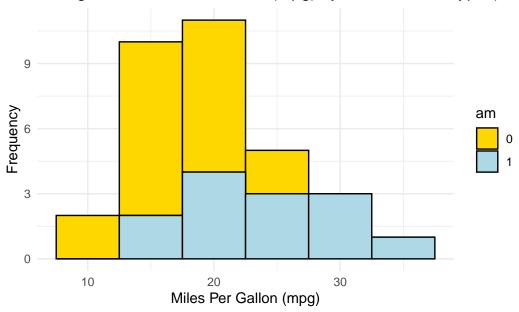

### 13.1.2 Histograms across one Category using ggplot2

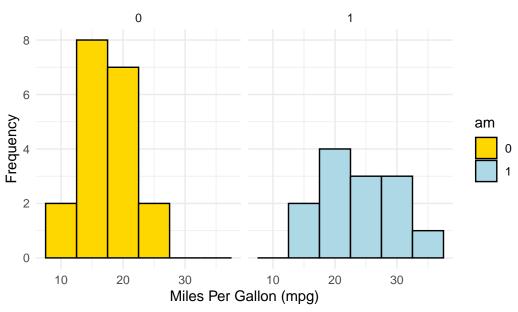

• Visualizing histograms of car milegage (mpg) broken down by transmission (am=0,1)

## Histogram of Miles Per Gallon (mpg) by Transmission Type (am)

• **Discussion**: If we want separate histograms, we can set facet\_wrap(~ am)

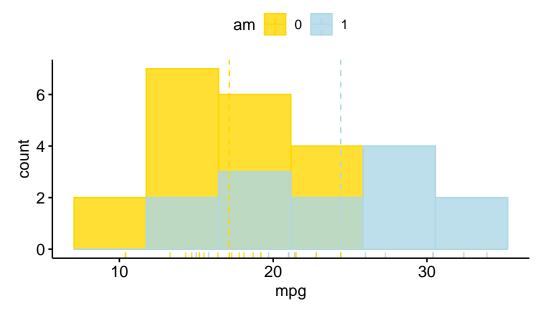

# Histogram of Miles Per Gallon (mpg) by Transmission Type (am)

### 13.1.2.1 Histogram across one Category using ggpubr

```
library(ggpubr)
gghistogram(tb,
    x = "mpg",
    bins = 6,
    add = "mean",
    rug = TRUE,
    color = "am",
    fill = "am",
    alpha = 0.8,
    palette = c("gold", "lightblue"),
    title = "Histogram of Mileage (mpg) by Transmission (am=0,1)")
```

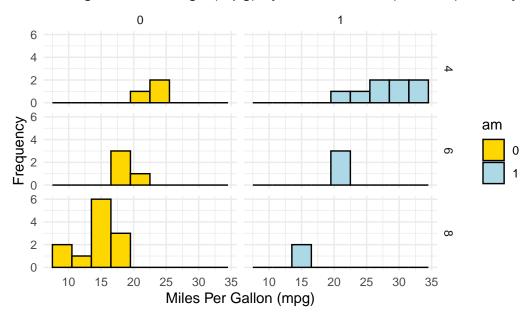

# Histogram of Mileage (mpg) by Transmission (am=0,1)

# 13.1.3 Histograms across two Categories using ggplot2

• Visualizing histograms of car milegage (mpg) by transmission (am=0,1) and cylinders (cyl=4,6,8)

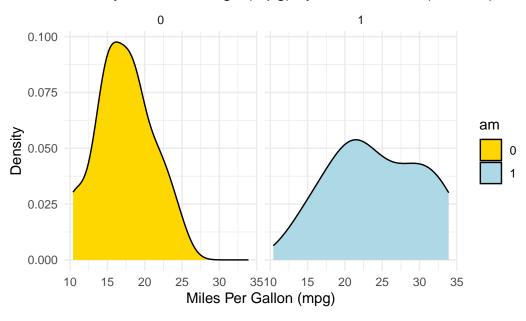

## Histogram of Mileage (mpg) by Transmission (am=0,1) and Cylir

### 13.1.4 PDF across one Category using ggplot2

• Visualizing the Probability Density Functions (PDF) of car milegage (mpg) by transmission (am=0,1)

### Density Plot of Mileage (mpg) by Transmission (am=0,1)

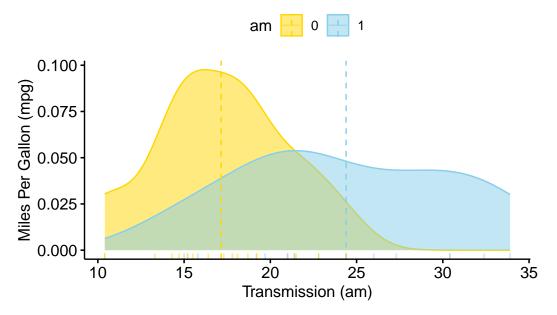

#### 13.1.4.1 PDF across one Category using ggpubr

• The provided R code creates a Boxplot of the mpg (miles per gallon) variable in the tb dataset, using the ggboxplot() function from the ggpubr package.

```
library(ggpubr)
ggdensity(tb,
    x = "mpg",
    color = "am" ,
    fill = "am",
    add = "mean",
    rug = TRUE,
    palette = c("gold", "skyblue"),
    title = "PDF of Mileage (mpg) by Transmission (am=0,1), using ggpubr::ggdensity(
    ylab = "Miles Per Gallon (mpg)",
    xlab = "Transmission (am)"
)
```

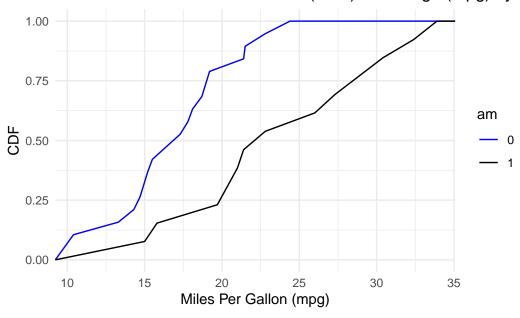

# PDF of Mileage (mpg) by Transmission (am=0,1), using

#### 13.1.5 CDF across one Category using ggplot2

• Visualizing the Cumulative Density Functions (CDF) of car milegage (mpg) by transmission (am=0,1)

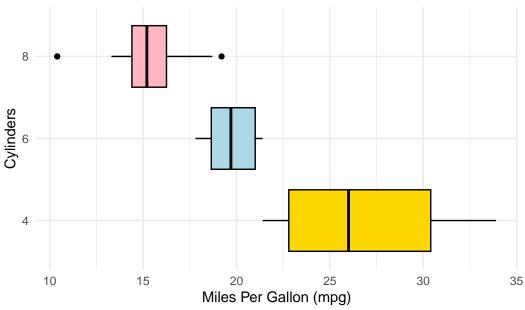

# Cumulative Distribution Function (CDF) of Mileage (mpg) by Ti

### 13.1.6 Box Plot across one Category using ggplot2

• Visualizing Boxplots of car milegage (mpg) broken down by cylinders (cyl=4,6,8)

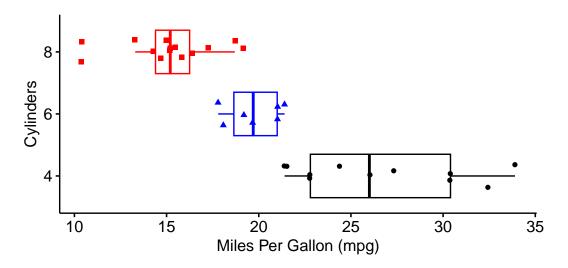

#### 13.1.6.1 Box Plot across one Category using ggpubr

• The provided R code creates a Boxplot of the mpg (miles per gallon) variable in the tb dataset, using the ggboxplot() function from the ggpubr package.

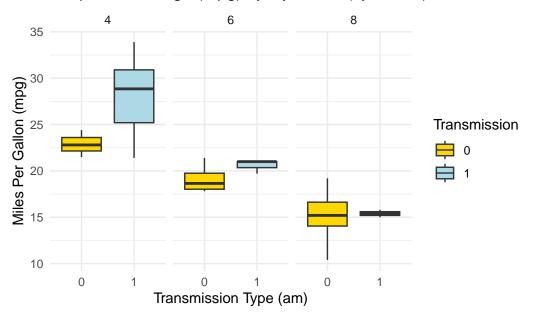

# Boxplot of Mileage (mpg) by Cylinders (cyl=4,6,8), using gc

#### 13.1.7 Box Plot across two Categories using ggplot2

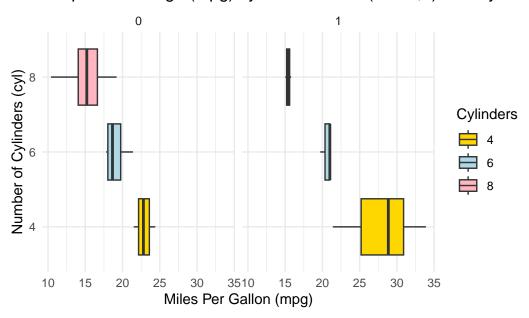

• Visualizing Boxplots of car milegage (mpg) broken down by cylinders (cyl=4,6,8) and Transmission (am=0,1)

# Boxplot of Mileage (mpg) by Cylinders (cyl=4,6,8) and Transmis

#### Alternately:

### Boxplot of Mileage (mpg) by Transmission (am=0,1) and Cylinde

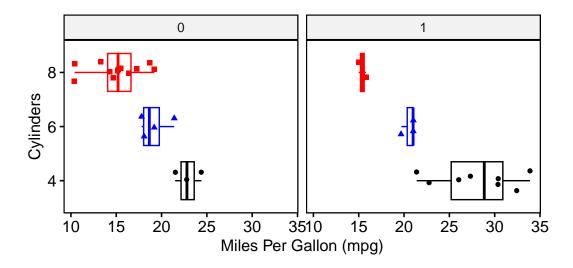

#### 13.1.7.1 Box Plot across two Categories using ggpubr

• The provided R code creates Boxplots of the mpg (miles per gallon) variable in the tb dataset, using the ggboxplot() function from the ggpubr package.

# Boxplot of Mileage by Cylinders, Transmission, with ggpubr

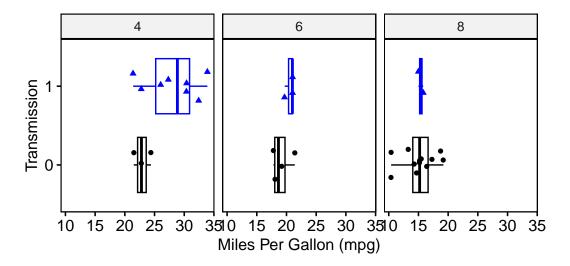

```
library(ggpubr)
ggboxplot(tb,

y = "mpg",
 x = "am",
 color = "am",
 fill = "white",
 palette = c("black", "blue"), # assuming am has 2 levels; adjust as needed
 shape = "am",
 orientation = "horizontal",
 add = "jitter", #jitter helps display the data points
 facet.by = "cyl", #split data by "cyl"
 title = "Boxplot of Mileage by Transmission, Cylinders, with ggpubr::ggboxplot()
 ylab = "Miles Per Gallon (mpg)",
 xlab = "Transmission"
)
```

# Boxplot of Mileage by Transmission, Cylinders, with ggpubr

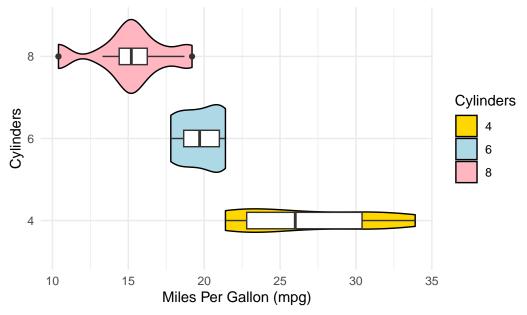

#### 13.1.8 Violin Plot across one Category using ggplot2

• We can embed boxplots within the above Violin plots, as follows.

# 13.2 Summarizing Continuous Data using dplyr and ggplot2

#### 13.2.1 Across one Category using dplyr and ggplot2

- 1. Calculating the mean and standard deviation
- We demonstrate the bivariate relationship between Miles Per Gallon (mpg) and Cylinders (cyl) using ggplot2.

Table 13.1: Summary Statistics of Mileage (mpg) by Cylinders (cyl=4,6,8)

cyl	Mean_mpg	SD_mpg
4	26.66	4.51

cyl	Mean_mpg	SD_mpg
6	19.74	1.45
8	15.10	2.56

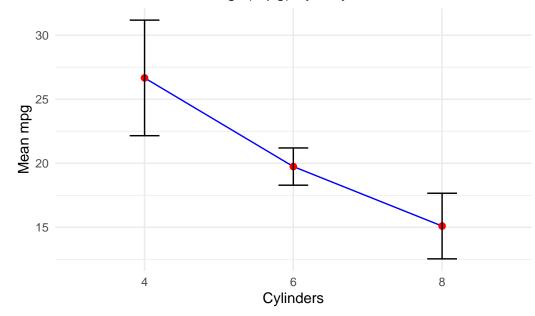

#### 2. Discussion:

- In this code, we use the pipe operator %\>% to perform a series of operations. We first group the data by the cyl column using the group\_by() function. We then use summarise() to apply the mean() and sd() functions to the mpg column.
- The results are stored in new columns, aptly named Mean\_mpg and SD\_mpg.
- We set na.rm = TRUE in both mean() and sd() function calls, to remove any missing values before calculation.
- The data resulting from the above code consists of grouped cylinder counts (cyl), their corresponding mean miles per gallon (Mean\_mpg), and the standard deviation of miles per gallon (SD\_mpg).[1]

#### 3. Visualizing the mean and standard deviation

• A simple way to visualize this data is to create a **line plot** for the mean miles per gallon with **error bars** indicating the standard deviation. Here is an example of how we could do this with **ggplot2**:

### Mean and SD of Mileage(mpg) by #Cylinders

#### 4. Discussion:

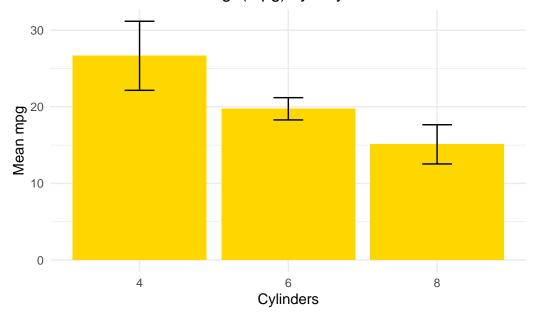

- aes(x = cyl, y = Mean\_mpg) assigns the cyl values to the x-axis and Mean\_mpg to the y-axis.
- geom\_line(group=1, color = "blue") adds a blue line connecting the data points.
- geom\_point(size = 2, color = "red") adds red points for each data point.
- geom\_errorbar(aes(ymin = Mean\_mpg SD\_mpg, ymax = Mean\_mpg + SD\_mpg), width = .2, colour = "black") adds error bars, where the error is the standard deviation.
- The ymin and ymax arguments define the range of the error bars.
- labs(x = "Cylinders", y = "Mean mpg") labels the x and y axes.
- theme\_minimal() applies a minimal theme to the plot.

#### 5. Visualizing the mean and standard deviation - Alternate Method

• An alternate method is to visualize this mean by creating a **bar plot**, with **error bars** indicating the standard deviation. Here is an example of how we could do this with ggplot2:

```
library(ggplot2)
# mpg plot
```

### Mean and SD of Mileage(mpg) by #Cylinders

#### 6. Discussion:

- ggplot(s1, aes(x = cyl, y = Mean\_mpg)): The ggplot() function initializes a ggplot object using dataframe s1 and mapping aesthetic elements. Here, aes(x = cyl, y = Mean\_mpg) specifies that the x-axis represents cyl (number of cylinders) and the y-axis represents Mean\_mpg (mean miles per gallon).
- geom\_bar(stat = "identity", fill = "gold"): The geom\_bar() function is used to create a bar chart. Setting stat = "identity" indicates that the heights of the bars represent the values in the data (in this case, Mean\_mpg). The fill = "gold" argument sets the color of the bars.

- geom\_errorbar() adds error bars to the plot. The arguments aes(ymin = Mean\_mpg SD\_mpg, ymax = Mean\_mpg + SD\_mpg) set the bottom (ymin) and top (ymax) of the error bars to represent one standard deviation below and above the mean, respectively.
   width = .2 sets the horizontal width of the error bars.
- labs(x = "Cylinders", y = "Mean mpg"): The labs() function is used to specify the labels for the x-axis and y-axis.
- theme\_minimal(): The theme\_minimal() function is used to set a minimalistic theme for the plot.
- 7. We extend this code to demonstrate how to measure the bivariate relationships between multiple continuous variables from the mtcars data and the categorical variable number of Cylinders (cyl), using ggplot2. Specifically, we want to measure the mean and SD of continuous variables (i) Miles Per Gallon (mpg); (ii) Weight (wt); (iii) Horsepower (hp) across the number of Cylinders (cyl).

```
s3 <- tb %>%
  group_by(cyl) %>%
  summarise(
    Mean_mpg = mean(mpg, na.rm = TRUE),
    SD_mpg = sd(mpg, na.rm = TRUE),
    Mean_wt = mean(wt, na.rm = TRUE),
    SD_wt = sd(wt, na.rm = TRUE),
    Mean_hp = mean(hp, na.rm = TRUE),
    SD_hp = sd(hp, na.rm = TRUE)
    )
kable(s3,
    digits=2,
    caption = "Summary of Mileage (mpg), Weight (wt), Horsepower (hp) by Cylinders (cyl=
```

Table 13.2: Summary of Mileage (mpg), Weight (wt), Horsepower (hp) by Cylinders (cyl=4,6,8)

cyl	Mean_mpg	SD_mpg	Mean_wt	SD_wt	Mean_hp	SD_hp
4	26.66	4.51	2.29	0.57	82.64	20.93
6	19.74	1.45	3.12	0.36	122.29	24.26
8	15.10	2.56	4.00	0.76	209.21	50.98

#### 8. Discussion:

library(dplyr)

• With tb %>%, we indicate that we are going to perform a series of operations on the tb

data frame. The group\_by(cyl) groups the data by the cyl variable.

- The summarise() function calculates the mean and standard deviation (SD) of three variables (mpg, wt, and hp). Thena.rm = TRUE argument inside mean() and sd() functions is used to exclude any NA values from these calculations.
- The resulting calculations are assigned to new variables (Mean\_mpg, SD\_mpg, Mean\_wt, SD\_wt, Mean\_hp, and SD\_hp) which will be the columns in the summarised data frame.
- To summarize, this script groups the data in the tb tibble by cyl and then calculates the mean and standard deviation of the mpg, wt, and hp variables for each group. [1]

#### 13.2.2 Across two Categories using ggplot2

1. We demonstrate the relationship between Miles Per Gallon (mpg) and Cylinders (cyl) and Transmission type (am) using ggplot2. Recall that a car's transmission may be automatic (am=0) or manual (am=1).

`summarise()` has grouped output by 'cyl'. You can override using the `.groups` argument.

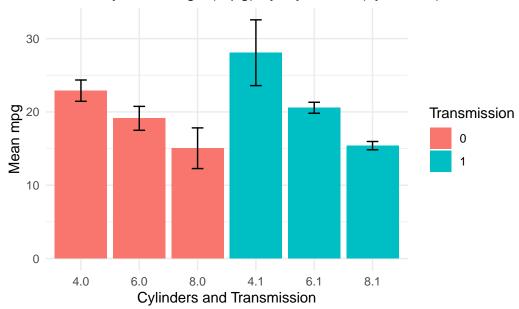

Table 13.3: Summary of Mileage (mpg) by Cylinders (cyl=4,6,8) and Transmission (am=0,1)

cyl	am	$Mean\_mpg$	$SD_mpg$
$\overline{4}$	0	22.90	1.45
4	1	28.08	4.48
6	0	19.12	1.63
6	1	20.57	0.75
8	0	15.05	2.77
8	1	15.40	0.57

#### 2. Discussion:

- The above code provides the mean and standard deviation of mpg for each unique combination of cyl and am.
- Here is how it can be visualized:

# Summary of Mileage (mpg) by Cylinders (cyl=4,6,8) and Transn

3. In the below code, the order of the variables is reversed - the data is first grouped by am, then by cyl. So, the function first sorts the data by the am variable, and within each am group, it further groups the data by cyl.

`summarise()` has grouped output by 'am'. You can override using the `.groups` argument.

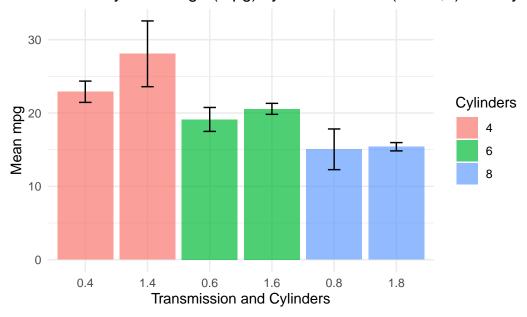

Table 13.4: Summary of Mileage (mpg) by Transmission (am=0,1) and Cylinders (cyl=4,6,8)

am	cyl	Mean_mpg	SD_mpg
0	4	22.90	1.45
0	6	19.12	1.63
0	8	15.05	2.77
1	4	28.08	4.48
1	6	20.57	0.75
1	8	15.40	0.57

• Here is how it can be visualized:

```
position = position_dodge(.9)) +
labs(x = "Transmission and Cylinders",
    y = "Mean mpg",
    fill = "Cylinders",
    title = "Summary of Mileage (mpg) by Transmission (am=0,1) and Cylinders (cyl=4,6,8)
theme_minimal()
```

# Summary of Mileage (mpg) by Transmission (am=0,1) and Cylir

4. The following code produces a new data frame that contains the mean and standard deviation of the continuous variables mpg, wt, and hp for each combination of the factor variables am and cyl. [1]

```
s6 <- tb %>%
  group_by(am, cyl) %>%
  summarise(
    Mean_mpg = mean(mpg, na.rm = TRUE),
    SD_mpg = sd(mpg, na.rm = TRUE),
    Mean_wt = mean(wt, na.rm = TRUE),
    SD_wt = sd(wt, na.rm = TRUE),
    Mean_hp = mean(hp, na.rm = TRUE),
    SD_hp = sd(hp, na.rm = TRUE)
)
```

`summarise()` has grouped output by 'am'. You can override using the `.groups` argument.

```
kable(s6,
     digits=2, caption = "Summary of Mileage (mpg) by Transmission (am=0,1) and Cylinder
```

Table 13.5: Summary of Mileage (mpg) by Transmission (am=0,1) and Cylinder (cyl=4,6,8)

am	cyl	Mean_mpg	SD_mpg	Mean_wt	$SD_wt$	Mean_hp	SD_hp
0	4	22.90	1.45	2.94	0.41	84.67	19.66
0	6	19.12	1.63	3.39	0.12	115.25	9.18
0	8	15.05	2.77	4.10	0.77	194.17	33.36
1	4	28.08	4.48	2.04	0.41	81.88	22.66
1	6	20.57	0.75	2.76	0.13	131.67	37.53
1	8	15.40	0.57	3.37	0.28	299.50	50.20

# 14 14: Continuous x Continous data (1 of 2)

Sep 17, 2023

### 14.1 Exploring bivariate Continuous x Continuous data

This chapter explores how to summarize and visualize the interaction between *bivariate continuous data* using correlation analysis, scatter plots, scatter plot matrices and other such techniques.

Data: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

# Load the required libraries, suppressing annoying startup messages

```
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
  library(tibble, quietly = TRUE, warn.conflicts = FALSE)
  library(knitr, quietly = TRUE, warn.conflicts = FALSE)
  library(ggplot2, quietly = TRUE, warn.conflicts = FALSE)
  library(car, quietly = TRUE, warn.conflicts = FALSE)
  library(psych, quietly = TRUE, warn.conflicts = FALSE)
  library(GGally, quietly = TRUE, warn.conflicts = FALSE)
Registered S3 method overwritten by 'GGally':
  method from
  +.gg
        ggplot2
  # Read the mtcars dataset into a tibble called tb
  data(mtcars)
  tb <- as_tibble(mtcars)</pre>
  # Convert relevant columns into factor variables
  tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
  tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
  tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
  tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears
```

```
# Directly access the data columns of tb, without tb$mpg
attach(tb)
```

The following object is masked from package:ggplot2:

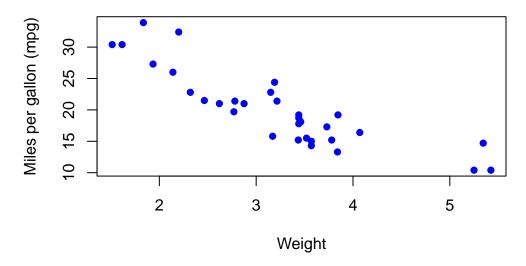

mpg

## 14.2 Scatterplots

- 1. A scatter plot is used to display the relationship between **two continuous variables**. It is a graphical representation of a bivariate distribution, where the values of two variables are plotted as points on a two-dimensional coordinate system.
- 2. A scatter plot can be used to **identify trends**, **clusters**, and other patterns in the data. It is also useful for detecting the presence of any **outliers** or **influential observations** that may affect the analysis. [1]
- 3. To create a scatter plot of mpg (miles per gallon) against wt (weight) in the mtcars data set, we can use the following code:

#### 14.2.1 Scatterplot using plot()

## Scatter Plot of Mileage vs. Weight

#### 4. Discussion:

- This code will create a scatter plot of mpg against wt using the plot() function.
- The main argument adds a title to the plot, the xlab and ylab arguments add axis labels
- The pch argument sets the shape of the points to a solid circle. pch = 15 gives a filled square. Recall other popular values: pch = 16 gives a filled circle, pch = 17 gives a filled triangle (pointing upwards), pch = 18 gives a filled diamond, pch = 19 gives a solid circle, pch = 20 gives a filled bullet (smaller than pch = 19)
- the col argument specifies the color of the data points. Recall we can use any named color in R, or we can use hexadecimal color codes. For instance, col = "#FF0000" would give us red points. [2]

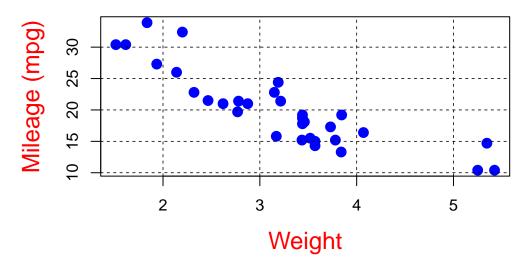

#### 5. Personalizing Scatter Plots

• We can personalize the appearance of the scatterplot in a variety of additional ways.

```
cex.lab=1.5,
  col.main="darkgreen",
  cex.main=2,
  bg = "gray")

# Add a grid
grid(col = "black",
  lty = "dashed",
  lwd = 0.8)
```

# Scatter Plot of MPG vs. Weight

#### 6. Discussion

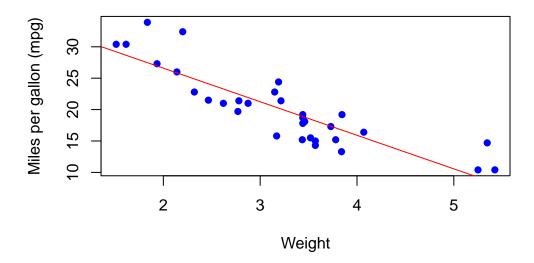

- Point Size: In the second plot, the size of the points is 1.5 times the default size (cex = 1.5), while in the first plot, the size of the points is the default size as cex is not specified.
- Axis Labels' Color and Size: The second plot has red-colored, larger size axis labels (col.lab="red", cex.lab=1.5), while the first plot uses the default color and size as these parameters are not specified.
- Title's Color and Size: The second plot has a dark green title that is twice the default size (col.main="darkgreen", cex.main=2), while the first plot uses the default color and size for the title as these parameters are not specified.
- Background Color: The second plot has a light gray background (bg = "lightgray"), while the first plot uses the default background color as the bg parameter is not specified.

• Grid: The second plot includes a grid with gray dotted lines (grid(col = "gray", lty = "dotted", lwd = 0.5)), while the first plot does not have a grid as the grid() function is not called. [2]

#### 7. Scatterplot with best fit line

• We can add a line of best fit (a regression line) to your scatterplot using the abline() and lm() functions. lm() is used to fit linear models, and abline() adds a straight line to the plot.

## Scatter Plot of Mileage vs. Weight

#### 8. Discussion:

• lm(tb\$mpg ~ tb\$wt) fits a linear model predicting mpg from wt. The ~ operator is a formula operator in R that separates the response variable (on the left of ~) from the

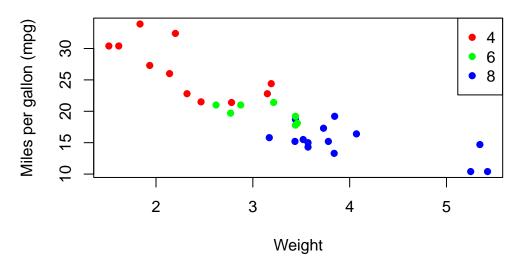

predictor variables (on the right of ~). abline(fit, col = "red") subsequently adds the regression line to the plot, drawn in red color. [3]

#### 9. Visualizing Continuous x Continuous x Categorical data

• Consider the issue of visualizing two continuous variables wt (Weight and mpg (Miles per gallon) for different levels of a categorical variable cyl (Cylinders).

```
# Create the scatterplot with points colored by cyl
plot(tb$wt,
    tb$mpg,
    main = "Scatter Plot of Mileage vs. Weight for cylinders (cyl=4,6,8)",
    xlab = "Weight", ylab = "Miles per gallon (mpg)",
    pch = 16,
    col=c("red", "green", "blue")[tb$cyl]
    )
# Add a legend
legend("topright",
    legend = levels(tb$cyl),
    col = c("red", "green", "blue"),
    pch = 16)
```

## Scatter Plot of Mileage vs. Weight for cylinders (cyl=4,6,8

#### 10. Discussion

• In the snippet col=c("red", "green", "blue") [tb\$cyl], we assign the color of the data points according to the cyl variable. It translates to distinct colors for different cyl values in the plot.

• Moreover, when we incorporate the legend() function with parameters such as "topright", we place a legend at the top-right corner of the plot. The identifiers and color scheme in the legend correspond to the unique values of the cyl variable. [2]

### 14.3 Scatterplot Matrix

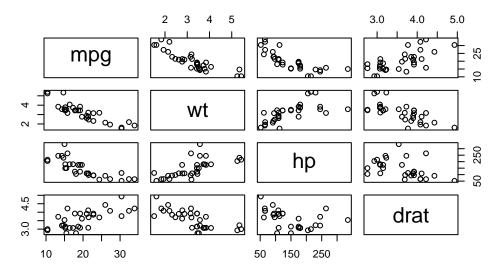

- 1. A scatter plot matrix, also known as a pairs plot or **SPLOM**, is a powerful visual tool that helps us in depicting the **pair-wise relationships** among a group of variables. In this matrix, every distinct variable from the dataset is charted against each other in a grid-like structure. This enables us to delve into the associations between variable pairs and identify possible trends or patterns in the dataset.
- 2. When dealing with multivariate datasets, scatter plot matrices can be remarkably handy. They equip us with a rapid way to **discern potential correlations among variable pairs** whether they are strong, weak, or non-existent. It's also a convenient method to spot non-linear relationships between variables. In addition, it's a beneficial tool to recognize outliers or peculiar data points and to observe clusters or collections of observations. [4]

#### 14.3.1 Scatterplot Matrix using pairs()

1. The following R code creates a scatter plot matrix, also known as a pairs plot, for four variables: mpg (miles per gallon), wt (weight), hp (horsepower), and drat (rear axle ratio). This is performed on the data stored in the tb data frame.

```
# scatter plot matrix for mpg, wt, hp, drat
columns = c("mpg","wt","hp","drat")
pairs(tb[,columns],
    main = "Scatter Plot Matrix for mpg, wt, hp, drat"
)
```

## Scatter Plot Matrix for mpg, wt, hp, drat

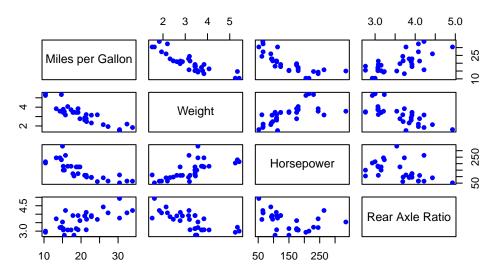

#### 2. Discussion:

- The pairs() function in R is designed to take a subset of the tb data frame consisting of the columns specified in the columns vector and construct a matrix of scatter plots.
- The plots are arranged in a grid format, where the variable for each row is plotted against the variable for each column. [5]

#### 3. Personalizing Scatterplot Matrix using pairs()

```
# scatter plot matrix for mpg, wt, hp, drat
pairs(tb[,c("mpg","wt","hp","drat")],
    main = "Scatter Plot Matrix for mpg, wt, hp, drat",
    pch = 19,
    labels = c("Miles per Gallon", "Weight", "Horsepower", "Rear Axle Ratio"),
    col = c("blue"),
    cex = 0.8
    )
```

## Scatter Plot Matrix for mpg, wt, hp, drat

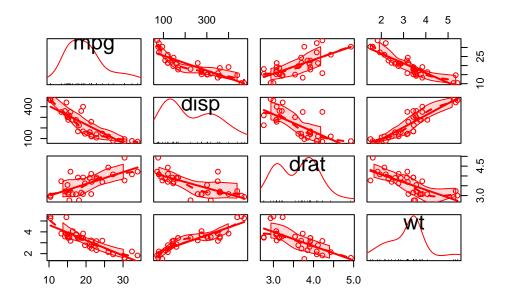

#### 4. Discussion:

- **Symbol**: The **pch** parameter is used to specify the symbol that represents data points in a plot.
- Labels: The labels parameter lets us customize the variable labels that appear on the diagonal:
- Color: We can specify different colors for the points in each scatter plot with the col parameter.
- Point Size: The cex parameter controls the size of the points in the scatter plot.

#### 14.3.2 Scatter Plot Matrix using scatterplotMatrix() from package car

1. The following code creates an alternate scatterplot matrix for each pair of the variables mpg, disp, drat, and wt, allowing us to explore the relationships among these four variables.

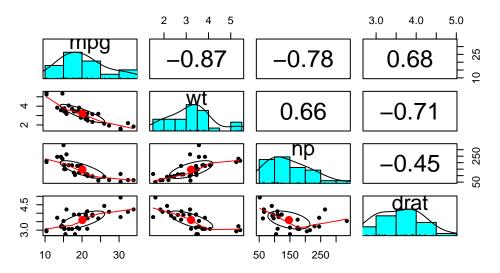

#### 2. Discussion:

- The car package, short for Companion to Applied Regression, contains numerous functions and datasets that are helpful for regression analysis.
- For creating a scatterplot matrix, we use the scatterplotMatrix() function.
- Here, the data argument specifies the data frame we are working with, tb.
- The formula ~ mpg + disp + drat + wt indicates the variables to be included in the scatter plot matrix. Recall mpg, disp, drat, and wt represent miles per gallon, displacement, rear axle ratio, and weight, respectively.
- The col argument is used to set the color of the points in the scatter plots. Here, all points are colored red. [3]

#### 14.3.3 Scatter Plot Matrix using pairs.panels() in package psych

## **Scatterplot Matrix**

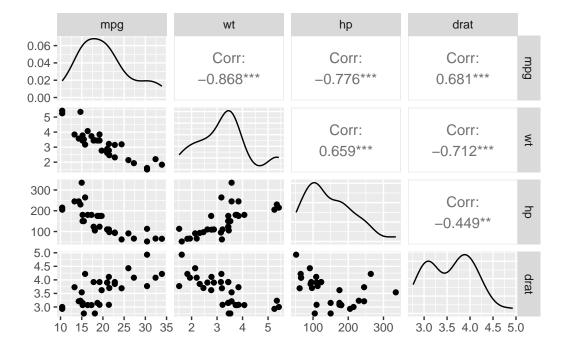

- The psych package contains a variety of functions useful for psychological, psychometric, and personality research.
- We utilize the pairs.panels() function from the psych package to create a scatterplot matrix. This function is very helpful as it produces:
  - Histograms: The diagonal often contains histograms or density plots of the individual variables. This provides insights about the distribution of each variable.
  - Scatterplots: The lower triangle (below the diagonal) of the plot matrix contains scatterplots of each variable against the other. This helps to visualize the bivariate relationships between variables.
  - Correlation Coefficients: The upper triangle (above the diagonal) often contains correlation coefficients or other statistics that describe the relationship between the two variables. The size (and sometimes color) of these numbers typically changes based on the strength of the correlation.
  - Red Dot: In the scatterplots of the lower triangle, the red dot signifies the bivariate mean of the two variables being plotted. In other words, it represents the average value on the x-axis and the average value on the y-axis. The red dot helps you to quickly gauge where the center of the data is in relation to the scatter of the rest of the points. If the red dot (bivariate mean) is centrally located, it may suggest that the variables are symmetrically distributed around their means. If it's located towards one of the corners, it could suggest a skew in the data or a strong correlation between the variables.

- tb[,c("mpg","wt","hp","drat")] in the code specifies the subset of the tb data frame that we want to include in the scatterplot matrix. In this case, it refers to the columns mpg (miles per gallon), wt (weight), hp (horsepower), and drat (rear axle ratio).
- The main parameter sets the main title for the plot, which in this instance is "Scatterplot Matrix". [6]

#### 14.3.4 Scatterplot Matrix Using ggpairs() in package GGally

```
# Load the GGally package
library(GGally)

# Create a scatterplot matrix using ggpairs()
ggpairs(tb[,c("mpg","wt","hp","drat")])
```

#### Discussion:

• The GGally package is an extension of the renowned ggplot2 package in R. It offers enhanced functionalities to create specific types of plots, especially when dealing with relationships between multiple variables.

- The ggpairs() function is a standout tool from GGally. It is designed to generate scatterplot matrices (often known as pairs plots) in a visually appealing format, providing insights into the pairwise relationships between variables.
- In the given code, the data frame being operated on is denoted by tb.
- The selection tb[,c("mpg","wt","hp","drat")] specifically picks out the columns named "mpg", "wt", "hp", and "drat". This means that our scatterplot matrix will show the relationships among these four variables. As a reminder, assuming typical automotive datasets: "mpg" might signify miles per gallon, "wt" would be the weight of the vehicle, "hp" indicates horsepower, and "drat" could represent the drive axle ratio.
- The output plot, produced by ggpairs(), will display a 4x4 grid. The diagonal of this grid usually portrays histograms or density plots for the individual variables, while the off-diagonal segments demonstrate scatter plots between two variables, giving a comprehensive overview of how each variable relates to the others.

## 14.4 Summary of Chapter

In this chapter, we explore the analysis of relationships between continuous variables. We begin by preparing a sample dataset and converting it to a structured format. As we move forward, we emphasize the importance of visual tools like scatter plots for understanding correlations and patterns between variables. These visual tools can reveal underlying trends, groupings, anomalies, and influential data points.

Using practical examples, we demonstrate how to create and customize these visualizations for clearer insights. Additionally, we introduce methods for enhancing scatter plots, including adding trend lines. The chapter also touches on the visualization of interactions between multiple variables, including the integration of categorical data, by means of color differentiation.

Transitioning from scatter plots, we explore the concept of a scatter plot matrix, or SPLOM. This tool is instrumental in showcasing pairwise relationships between a set of variables in a matrix format. Scatter plot matrices are incredibly helpful when navigating multivariate datasets, allowing quick visual recognition of potential correlations and relationships among variable pairs.

We then demonstrate how to create scatter plot matrices using R functions like pairs(), scatter-plotMatrix(), and pairs.panels(). Each method offers a different visual experience and comes with its unique set of features. For example, using pairs.panels() from the psych package, the matrix not only contains scatter plots but also histograms on the diagonal, correlation coefficients, and other enlightening statistical visualizations.

Overall, this chapter equips us with the knowledge to visualize and analyze bivariate continuous data effectively, aiding in more profound data interpretation and insights.

# 15 15: Continuous x Continuous data (2 of 2)

Sep 17, 2023.

# 15.1 Exploring bivariate Continuous x Continuous data, using ggplot2

This chapter demonstrates the use of the popular ggplot2 and ggpubr packages to further explore the interaction between bivariate continuous data.

Data: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

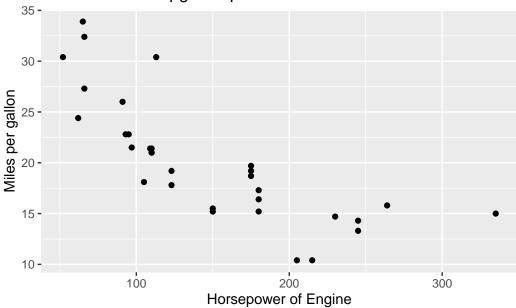

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(ggpubr, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
# Read the mtcars dataset into a tibble called tb
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears</pre>
```

#### 15.1.1 Scatterplot using ggplot2

```
ggplot(tb,
    aes(x = hp, y = mpg)) +
    geom_point() +
    xlab("Horsepower of Engine") +
```

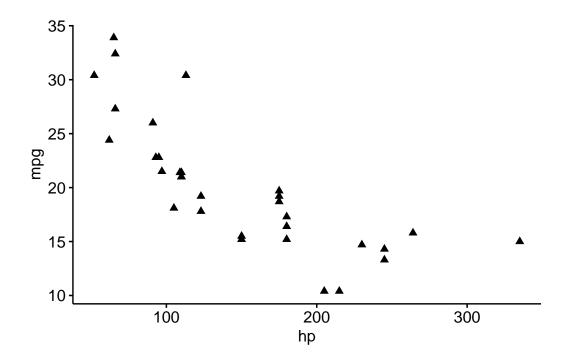

```
ylab("Miles per gallon") +
ggtitle("Scatter Plot of mpg vs. hp")
```

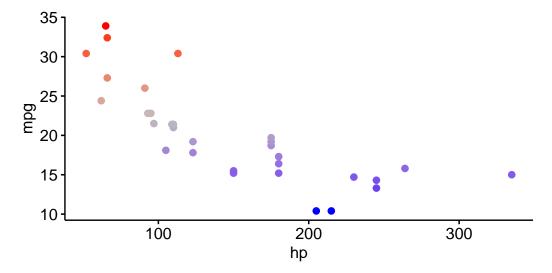

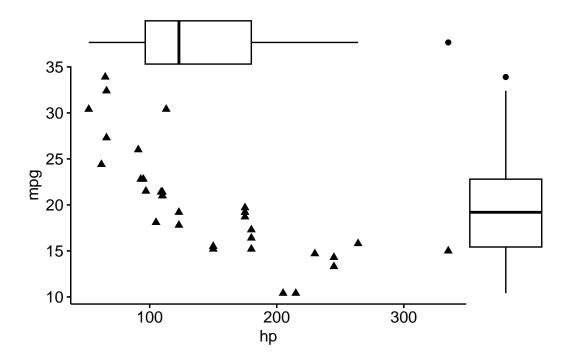

- The ggplot2 package uses a layering approach, enabling users to build plots incrementally, piece by piece, using a combination of data, aesthetics, and geometric objects.
- The function ggplot() initializes the plotting system. It requires a dataset to operate on and an aesthetic mapping to determine how data variables will be plotted. Here, the dataset is represented by tb.
- Inside the aes() function, which stands for aesthetics, the code specifies that the variable hp from the tb data frame will be plotted on the x-axis and the variable mpg will be plotted on the y-axis. Hence, the resulting plot will display a relationship between horsepower (hp) and miles per gallon (mpg).
- The geom\_point() function is an added layer, instructing ggplot2 to render the relationship between hp and mpg as a scatter plot, with individual data points being represented as points.
- The functions xlab() and ylab() are used to set custom labels for the x and y axes, respectively. In this code, the x-axis is labeled as "Horsepower of Engine" and the y-axis is labeled as "Miles per gallon".

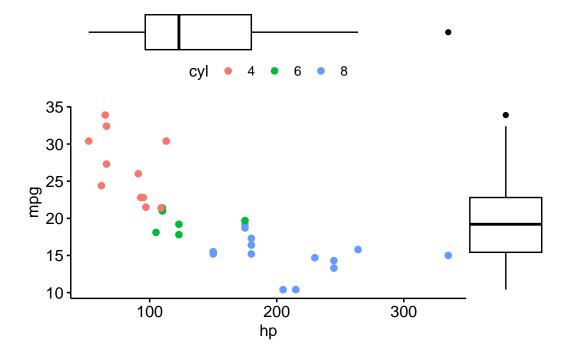

• Finally, the ggtitle() function is used to assign a title to the entire plot. In this instance, the title is set as "Scatter Plot of mpg vs. hp", clearly indicating the purpose and content of the visualization.

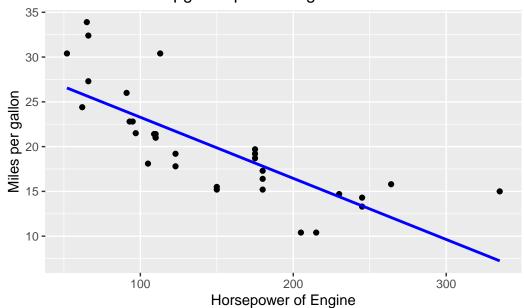

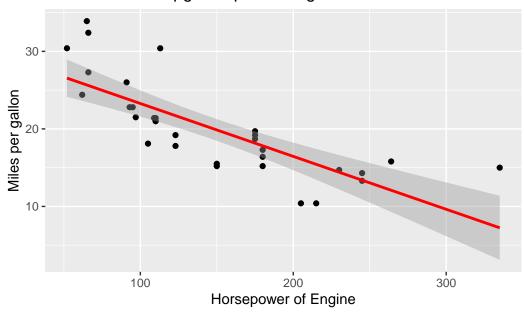

## 15.1.2 Scatterplot with Regression line using ggplot2

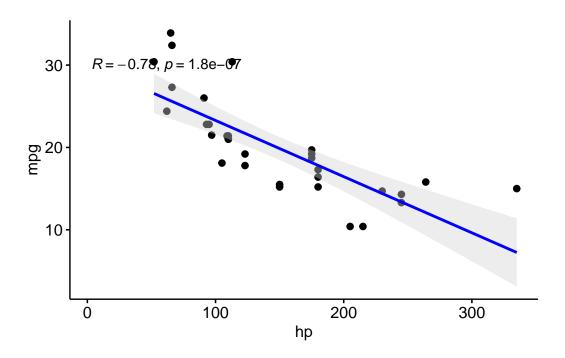

## Scatter Plot of mpg vs. hp with Regression Line

#### Scatter Plot of mpg vs. hp with Regression Line

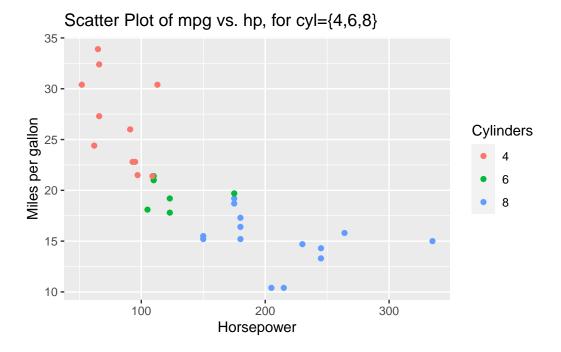

- geom\_smooth(method = "lm", se = FALSE, color = "blue"): This function adds a smoothed conditional mean.
  - The method = "lm" argument indicates that a linear model (i.e., a regression line) should be used for smoothing. This line will depict the overall trend in the data.
  - If se = FALSE then the standard error bands (which show the uncertainty around the regression line) aren't plotted. This determines whether or not the standard error bands (or confidence interval bands) are displayed around the smoothing line. In the case of linear regression (method = "lm"), these bands represent the 95% confidence interval around the predicted values. This means that if you were to repeatedly sample from the population and fit a regression model each time, you'd expect about 95% of the confidence intervals to contain the true regression line.

## 15.2 Scatterplots with Categorical Variables

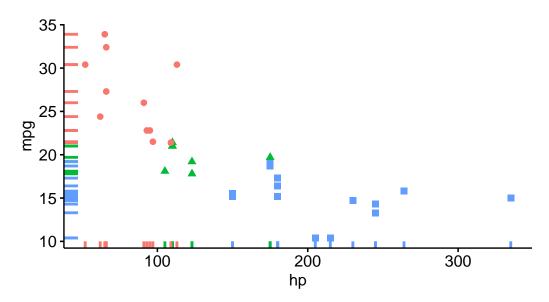

#### 15.2.1 Scatterplot colored by a Categorical variable, using ggplot()

This will create a scatterplot of miles per gallon (mpg) against horsepower (hp), with each point colored according to the number of cylinders (cyl) in the engine.

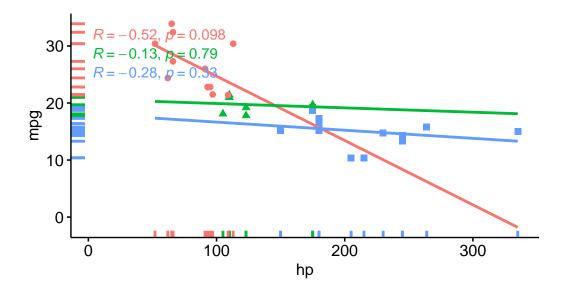

- The aes() function, short for aesthetics, designates the variables and their roles in the plot. In this code:
  - The hp variable is plotted on the x-axis.
  - The mpg variable is mapped to the y-axis.
  - The color attribute is set based on the cyl variable, which presumably indicates the number of cylinders in a car engine. The use of factor(cyl) ensures that the cyl variable is treated as a discrete factor rather than a continuous variable, which is essential for color differentiation.
- geom\_point() introduces a scatter plot layer, meaning that the relationship between hp and mpg will be represented using individual points, with each point's color reflecting the number of cylinders as specified in the aesthetic mapping.
- The labs() function provides a convenient way to label the axes. Here, the x-axis receives the label "Horsepower" and the y-axis is labeled "Miles per gallon".
- The scale\_color\_discrete() function customizes the color scale for discrete variables. By specifying the name argument as "Cylinders", it ensures that the legend accompanying the color scale in the plot will be labeled as "Cylinders", making it clear to viewers that the colors of the points represent different cylinder counts.

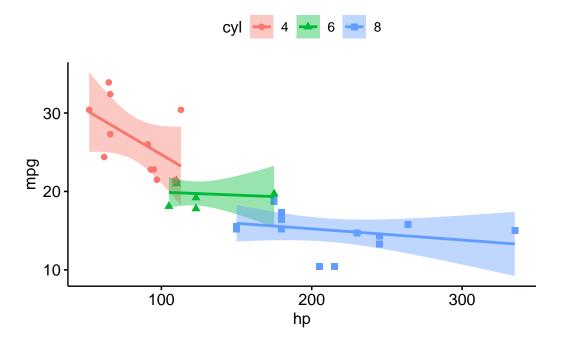

```
# Extending the regression line --> fullrange = TRUE
# Add marginal rug (marginal density) ---> rug = TRUE
ggscatter(tb,
          x = "hp", y = "mpg",
         add = "reg.line",
                                   # Add regression line
                                  # Color by groups "cyl"
         color = "cyl",
          shape = "cyl",
                                  # Change point shape by groups "cyl"
                                  # Extending the regression line
          fullrange = TRUE,
                                   # Add marginal rug
          rug = TRUE
          ) +
 stat_cor(aes(color = cyl),
           label.x = 3)
                                  # Add correlation coefficient
```

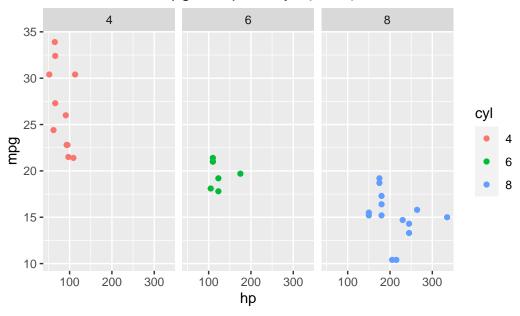

```
ggscatter(tb,
    x = "hp", y = "mpg",
    add = "reg.line", # Add regression line
    conf.int = TRUE, # Add confidence interval
    color = "cyl", # Color by groups "cyl"
    shape = "cyl" # Change point shape by groups "cyl"
)
```

## 15.2.2 Scatterplot faceted by a Categorical variable, using ggplot()

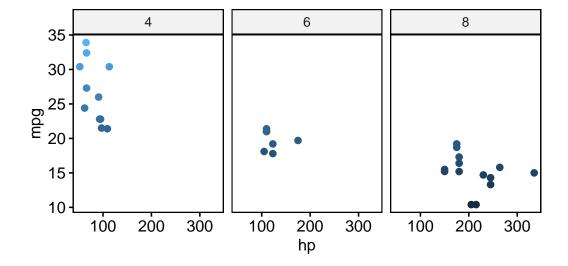

This will create a scatterplot of miles per gallon (mpg) against weight, with each plot faceted by the number of cylinders in the engine (cyl).

### Scatter Plot of mpg vs. hp, for cyl={4,6,8}

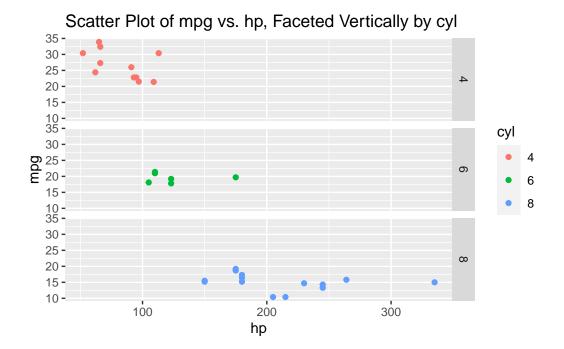

- The foundational layer is initialized with the ggplot() function. This function takes in a dataset, tb, and aesthetic mappings that determine how variables are displayed. In this piece of code:
  - hp is chosen to be plotted on the x-axis.
  - mpg is selected for the y-axis.
  - The color of the points will be determined by the cyl variable.
- The addition of the geom\_point() layer ensures that a scatter plot will represent the relationship between hp and mpg. Each point's color will correspond to the value of the cyl variable.
- The facet\_grid() function introduces the concept of faceting. Faceting divides a plot into multiple panels based on the levels of one or more factors. In this case, the plot is faceted horizontally (~ cyl), meaning that separate panels are created for each unique value of cyl. The . before the ~ indicates that there's no faceting vertically.
- Finally, the ggtitle() function provides the entire plot with a title, which is "Scatter Plot of mpg vs. hp, for cyl={4,6,8}". This title clearly communicates the main theme of the plot and indicates that it showcases relationships for cars with 4, 6, or 8 cylinders.

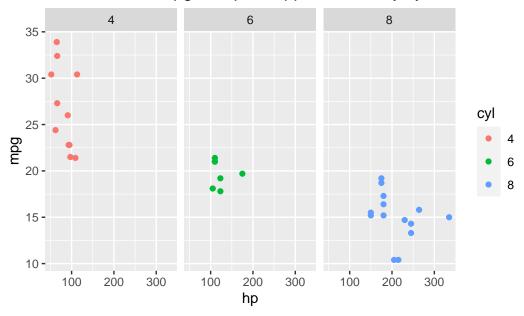

```
ggplot(tb,
    aes(x = hp,
        y = mpg,
        color = cyl)) +
    geom_point() +
    facet_grid(cyl ~ .) +
    ggtitle("Scatter Plot of mpg vs. hp, Faceted Vertically by cyl")
```

- The primary difference between the two code snippets lies in how the faceting is implemented using the facet\_grid() function.
- In the original code, facet\_grid(. ~ cyl) is used, which means the scatter plots are faceted horizontally based on the unique values of the cyl variable; each unique cylinder count gets its own column.
- Conversely, in the updated code with facet\_grid(cyl ~ .), the scatter plots are faceted vertically based on the unique values of the cyl variable; each unique cylinder count gets its own row.

```
ggplot(tb,
    aes(x = hp,
        y = mpg,
        color = cyl)) +
    geom_point() +
    facet_wrap(~ cyl, ncol = 3) +
    ggtitle("Scatter Plot of mpg vs. hp, Wrapped Facets by cyl")
```

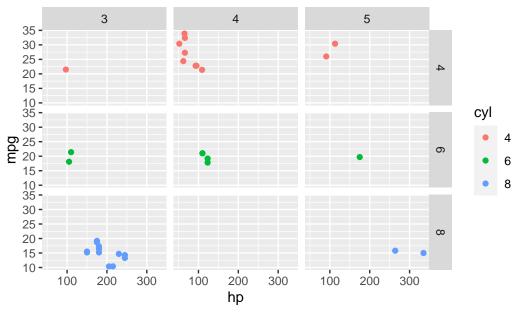

## Scatter Plot of mpg vs. hp, Wrapped Facets by cyl

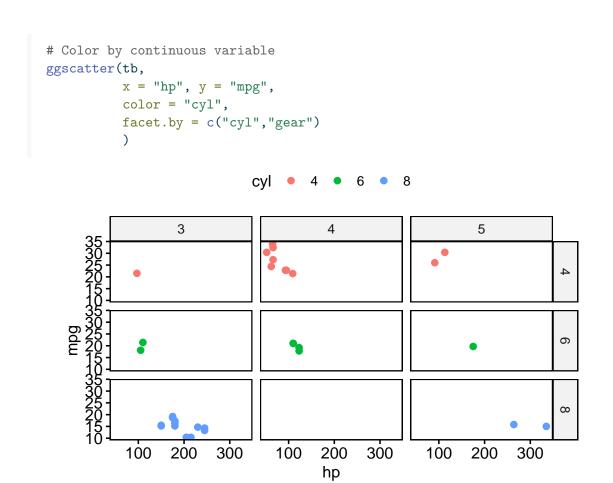

- This approach creates a wrapped grid of facets based on cyl.
- The ncol = 3 argument specifies that up to three facets will be placed in a row before wrapping to the next row. You can adjust this as needed based on the number of levels in the faceting variable and the desired layout.

```
ggplot(tb,
    aes(x = hp,
        y = mpg,
        color = cyl)) +
geom_point() +
facet_grid(cyl ~ gear) +
ggtitle("Scatter Plot of mpg vs. hp, Faceted by cyl and gear")
```

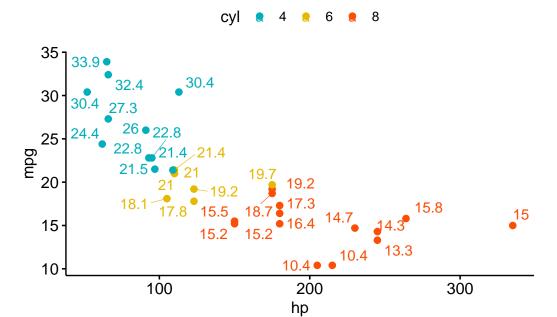

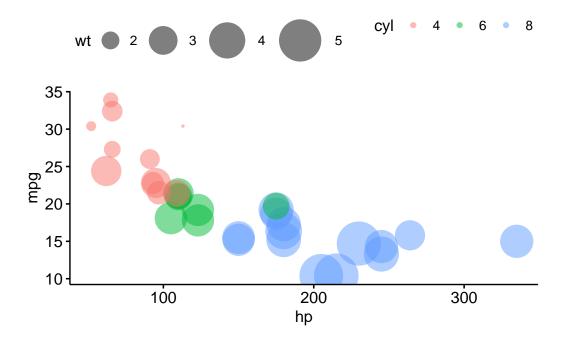

- In this code, within the aes() aesthetics function:
  - The variable hp is mapped to the x-axis.
  - The variable mpg is mapped to the y-axis.
  - The color of individual points is determined by the cyl variable, which probably represents the number of cylinders in an engine.
- The geom\_point() function is introduced to represent the relationship between hp and mpg as a scatter plot. The colors of the individual points will correspond to the values of the cyl variable.
- The facet\_grid(cyl ~ gear) function is the standout feature in this code. Here, the plots are faceted based on two categorical variables:
  - cyl, which is mapped to rows. Each unique value of cyl will generate a new row of plots.
  - gear, which is mapped to columns. Each unique value of gear will generate a new column of plots.
  - The resultant grid will represent combinations of cyl and gear values, with each cell
    in the grid showing the relationship between hp and mpg for a specific combination
    of cyl and gear.

## 16 16: Three Dimensions (3D)

Oct 01, 2023

## 16.1 Overview of R packages for 3D Plots

This chapter demonstrates how to create 3D plots in R.

#### ggplot2

The ggplot2 package in R is primarily designed for creating 2D plots. However, we can simulate 3D effects, even though it won't provide true 3D plots

#### scatterplot3d

The scatterplot3d package in R can be used to create 3D scatter plots. It is quite simple to use and can be a good choice for quick visualizations.

#### rgl

The rgl package in R is a powerful tool for creating interactive 3D plots. It allows real-time interaction with the plots, where users can zoom, rotate, and pan the visualization to explore the data in three dimensions. This package provides various functionalities to create a variety of 3D plots, including scatter plots, surface plots, line plots, bar plots

```
# Load the required libraries for 3D plots, suppressing annoying startup messages
library(scatterplot3d, quietly = TRUE, warn.conflicts = FALSE)
library(rgl, quietly = TRUE, warn.conflicts = FALSE)
```

**Data**: Suppose we run the following code to prepare the mtcars data for subsequent analysis and save it in a tibble called tb.

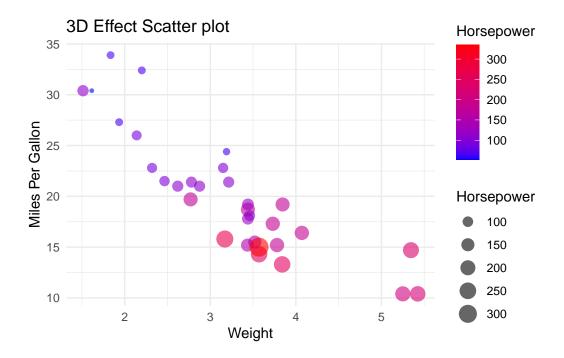

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE)
library(tibble, quietly = TRUE, warn.conflicts = FALSE)
library(ggplot2, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(ggpubr, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
# Read the mtcars dataset into a tibble called tb
```

```
data(mtcars)
tb <- as_tibble(mtcars)
# Convert relevant columns into factor variables
tb$cyl <- as.factor(tb$cyl) # cyl = {4,6,8}, number of cylinders
tb$am <- as.factor(tb$am) # am = {0,1}, 0:automatic, 1: manual transmission
tb$vs <- as.factor(tb$vs) # vs = {0,1}, v-shaped engine, 0:no, 1:yes
tb$gear <- as.factor(tb$gear) # gear = {3,4,5}, number of gears</pre>
```

## 16.2 3D Plots using ggplot2

The ggplot2 package in R cannot create true 3D plots. Here is how to simulate a 3D plot using ggplot2.

#### 16.2.1 Simulating 3D using ggplot2

#### Discussion:

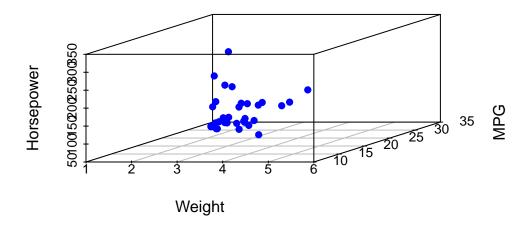

- The code provided simulates a 3D plot by exploiting visual cues and perceptual aspects of human vision. It uses the following strategies to simulate depth and give the perception of a three-dimensional plot on a two-dimensional surface:
- Size Encoding: The size = hp aesthetic in the aes() function maps the hp (horse-power) variable to the size of the points in the scatter plot. Points representing cars with higher horsepower appear larger, while those with lower horsepower appear smaller. This varying point size provides a depth cue, simulating the z-axis on a 2D surface.
- Color Encoding: The color = hp aesthetic assigns different colors to the points based on their horsepower values. The scale\_color\_gradient(low = "blue", high = "red") function further specifies that lower horsepower should be represented with blue, transitioning to red for higher horsepower. The gradient color scale serves as another depth cue, indicating that points of different colors are at different 'depths'.
- Alpha Transparency: The alpha = 0.6 parameter in the geom\_point() function adjusts the transparency of the points. This transparency allows for better visibility of overlapping points, giving a sense of depth where points are clustered.
- Axis Mapping: The x = wt and y = mpg within the aes() function map the weight of the cars to the x-axis and the miles per gallon to the y-axis. These two axes represent the spatial dimensions on the plotting surface.

- This plot has similarities to the classic bubble plot. The application of a color gradient gives the illusion of 3D.
- By combining these elements, the plot employs size, color gradient, and transparency to introduce visual cues of depth, effectively simulating a 3D effect on a 2D plotting surface. This enables the viewer to infer relationships among wt, mpg, and hp, even though the plot itself is inherently two-dimensional.

# 16.3 3D Plots using scatterplot3d

The \*scatterplot3d\*\* package can be used on the mtcars data to demonstrate visualization in 3 dimensions.

## 3D Scatter Plot of mtcars

#### **Discussion**:

• x = tb\$wt, y = tb\$mpg, and z = tb\$hp are used to map the wt, mpg, and hp columns from the tb tibble to the x, y, and z axes of the 3D scatter plot respectively.

- The xlab, ylab, and zlab parameters are used to label the x, y, and z axes.
- pch = 16 specifies the type of point to be used in the plot.
- color = "blue" sets the color of the points to blue.
- main is used to set the title of the plot.
- Overall, this code visualizes a 3D scatter plot demonstrating the relationships between wt, mpg, and hp in the mtcars dataset.

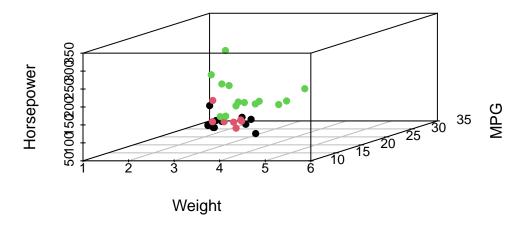

### 16.3.1 Variations of 3D Plots using scatterplot3d

Here are some variations and extensions of the original scatterplot3d code to demonstrate the versatility of 3D visualizations:

#### Color by a Variable:

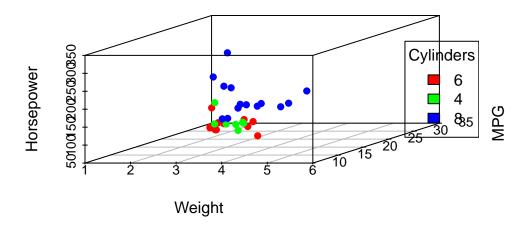

We can color points by a variable, for example, by the number of cylinders (cyl), which can reveal additional patterns in the data.

# 3D Scatter Plot Colored by Number of Cylinders

• We can add a legend for the color in the scatterplot3d plot by using a combination of the legend function and the colors argument.

# 3D Scatter Plot Colored by Number of Cylinders

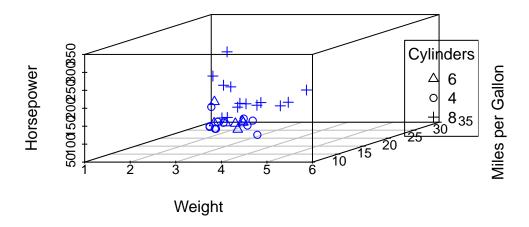

#### Discussion:

- We defined a color palette using the rainbow function based on the number of unique cylinder values in tb\$cyl.
- We then used this color palette to color the points in the scatter plot.
- Finally, we used the legend function to manually add a color legend to the right of the plot. The legend function takes the unique cylinder values as the labels for the legend and the colors from the color palette as the fill colors. The title of the legend is set to "Cylinders".

### Change Point Style:

We can change the point style to better distinguish between data points.

# 3D Scatter Plot with Different Point Styles

#### **Discussion**:

- This R code visualizes relationships among the wt, mpg, and hp columns from the tb tibble, with points having different shapes based on the number of cylinders (cyl).
- Creation of 3D Scatter Plot
  - sp34 <- scatterplot3d(...): This line initializes the creation of a 3D scatter plot and stores the result in the s3d variable.

- -x = tb\$wt, y = tb\$mpg, z = tb\$hp: These arguments define the variables that will be plotted on the x, y, and z axes, respectively.
- pch = as.numeric(tb\$cyl): This argument specifies the point shape (pch) to vary based on the cyl column, with different cylinders represented by different shapes.
- color = "blue": All points are colored blue.
- xlab, ylab, zlab: These arguments label the axes of the plot.
- main: This argument provides the main title of the plot.

# • Determination of Unique Cylinder Values and Shapes

- cylinders <- unique(tb\$cyl): This line identifies the unique values in the cylinders variable.</li>
- shapes <- as.numeric(cylinders): The unique cylinder values are converted to numeric form to determine the corresponding point shapes, which are stored in shapes.

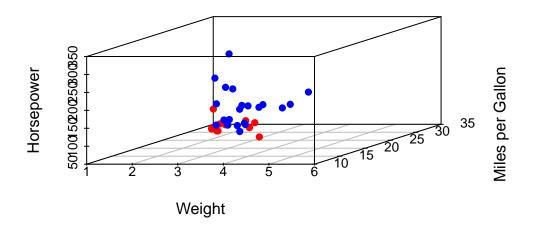

#### • Addition of Legend

- legend("right", ...): This function is used to add a legend to the right of the plot.
- legend = as.character(cylinders): This argument defines the labels of the legend, which are the unique cylinder values converted to character strings.
- pch = shapes: The point shapes corresponding to the unique cylinder values are used in the legend.
- title = "Cylinders": The title of the legend is set as "Cylinders".
- By executing this code, we get a 3D scatter plot with points having different shapes based on the number of cylinders, and a corresponding legend clarifying the representation of each shape.

#### **Highlight Specific Points:**

We can can highlight specific points, for example, cars with 4 cylinders, by changing their color or size.

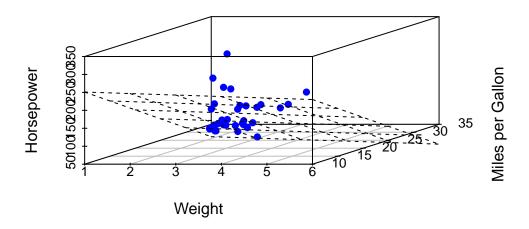

# **3D Scatter Plot Highlighting Specific Points**

# Add Regression Plane:

We can can fit a linear regression model and add the regression plane to the scatter plot.

# 3D Scatter Plot with Regression Plane

#### Discussion:

• This code snippet is used to create a 3D scatter plot and then fit a linear regression plane to the plotted data points.

#### • Fit a Linear Model

- model <- lm(hp ~ wt + mpg, data = tb): A linear model is fitted using the lm function with hp as the dependent variable and wt and mpg as the independent variables. The resulting model object is stored in the variable model.</p>

#### • Add a Regression Plane to the Plot

- sp36\$plane3d(model): The plane3d function is accessed from the s3d object and
  is used to add a regression plane to the existing 3D scatter plot. The plane is based
  on the coefficients of the linear model stored in model.
- The resulting output will be a 3D scatter plot visualizing the relationships among weight (wt), miles per gallon (mpg), and horsepower (hp), with a regression plane fitted to these points, representing the linear relationship between the dependent and independent variables.

# 17 Live Case: S&P500 (Overview)

Oct 09, 2023.

# 17.1 S&P 500

The S&P 500, also called the Standard & Poor's 500, is a stock market index that tracks the performance of 500 major publicly traded companies listed on U.S. stock exchanges. It serves as a widely accepted benchmark for assessing the overall health and performance of the U.S. stock market.

S&P Dow Jones Indices, a division of S&P Global, is responsible for maintaining the index. The selection of companies included in the S&P 500 is determined by a committee, considering factors such as market capitalization, liquidity, and industry representation.

The S&P is a float-weighted index, meaning the market capitalizations of the companies in the index are adjusted by the number of shares available for public trading. https://www.investopedia.com/terms/s/sp500.asp

The performance of the S&P 500 is frequently used to gauge the broader stock market and is commonly referenced by investors, analysts, and financial media. It provides a snapshot of how large-cap U.S. stocks are faring and is considered a reliable indicator of overall market sentiment.

Typically, the S&P 500 index consists of 500 stocks. However, in reality, there are actually 503 stocks included. This discrepancy arises because three of the listed companies have multiple share classes, and each class is considered a separate stock that needs to be included in the index.

#### Strengths:

- 1. **Diverse Representation**: The S&P 500 isn't fixated on a single industry. From technology to healthcare, it offers a panoramic view of various economic sectors, making it an inclusive representation of the U.S. corporate sector.
- 2. **Benchmark for Investors**: For many fund managers, outperforming the S&P 500 stands as a golden standard. It's a yardstick, establishing it as a critical touchstone for gauging investment success.

3. Liquidity and Visibility: Constituent companies enjoy high liquidity and are subject to rigorous screening processes, ensuring that the index represents financially viable entities.

#### Critiques:

- 1. Market Capitalization Weighting: The index is weighted by market capitalization, meaning companies with higher market values have a more pronounced effect on its performance. Critics argue this approach can skew perceptions, especially during market bubbles when certain sectors are overvalued.
- 2. **Exclusivity**: Despite its broad purview, 500 companies cannot encapsulate the entire U.S. economy. Many sectors, especially emerging industries or smaller businesses, might not be adequately represented.
- 3. **Potential for Complacency**: The prominence of the S&P 500 has led many investors to adopt passive investment strategies, tracking the index rather than actively managing portfolios. Detractors argue this might lead to market inefficiencies and reduced capital allocation efficacy.

While the S&P 500 remains an influential and pivotal tool for investors, its dominance prompts a double-edged sword of advantages and critiques. In a constantly evolving economic land-scape, understanding both its power and limitations is essential for informed financial decision-making.

# 17.2 S&P 500 Data

#### 17.2.1 Load some useful R packages

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE) # For data manipulation
library(tibble, quietly = TRUE, warn.conflicts = FALSE) # For data manipulation
library(ggplot2, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
```

```
library(ggpubr, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(gsheet, quietly = TRUE, warn.conflicts = FALSE) # For Google Sheets
library(rmarkdown, quietly = TRUE, warn.conflicts = FALSE) # For writing
library(knitr, quietly = TRUE, warn.conflicts = FALSE) # For tables
library(kableExtra, quietly = TRUE, warn.conflicts = FALSE) # For tables
```

## 17.2.2 Read the S&P500 data from a Google Sheet into a tibble

- 1. We will analyze a real-world, recent dataset containing information about the S&P500 stocks. The dataset is located in a Google Sheet and periodically updated.
- 2. The complete URL of the Google Sheet that has the data is https://docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM/docs.google.com/spreadsheets/d/11ahk9uWxMxdxyd/docs.google.com/spreadsheets
- 3. The Google Sheet ID is: 11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM. We can use the function gsheet2tbl in package gsheet to read the Google Sheet into a tibble, as demonstrated in the following code.

```
# Read S&P500 stock data present in a Google Sheet.
library(gsheet)
prefix <- "https://docs.google.com/spreadsheets/d/"
sheetID <- "11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM"
url500 <- paste(prefix,sheetID) # Form the URL to connect to
sp500 <- gsheet2tbl(url500) # Read it into a tibble called sp500</pre>
```

4. **Reference**: This data has been sourced from websites like Yahoo Finance and Trading View.com and it is current as of 10/9/2023

### 17.3 Review the S&P 500 data

1. The data corresponds to 503 companies that are part of the S&P500 and includes 36 data columns.

```
dim(sp500)
```

[1] 503 36

2. The first ten stocks in the S&P500 data, their Sector and their recent prices are as follows:

```
sp500 %>%
  select(Stock, Description, Sector, Date, Price) %>%
  head(10) %>%
  kable("html", caption = "The first 10 companies in the S&P500 dataset") %>%
  kable_styling()
```

Table 17.1: The first 10 companies in the S&P500 dataset

Stock	Description	Sector	Date	Price
A	Agilent Technologies, Inc.	Health Technology	10/9/2023	111.1
AAL	American Airlines Group, Inc.	Transportation	10/9/2023	12.5
AAPL	Apple Inc.	Electronic Technology	10/9/2023	171.2
ABBV	AbbVie Inc.	Health Technology	10/9/2023	146.0
ABNB	Airbnb, Inc.	Consumer Services	10/9/2023	130.6
ABT	Abbott Laboratories	Health Technology	10/9/2023	95.3
ACGL	Arch Capital Group Ltd.	Finance	10/9/2023	78.6
ACN	Accenture plc	Technology Services	10/9/2023	308.9
ADBE	Adobe Inc.	Technology Services	10/9/2023	512.4
ADI	Analog Devices, Inc.	Electronic Technology	10/9/2023	174.2

#### 3. Data Columns

• The data comprises of the following 36 columns:

### colnames(sp500)

- [1] "Date"
- [2] "Stock"
- [3] "Description"
- [4] "Sector"
- [5] "Industry"
- [6] "Market Capitalization"
- [7] "Price"
- [8] "52 Week Low"
- [9] "52 Week High"
- [10] "Return on Equity (TTM)"
- [11] "Return on Assets (TTM)"
- [12] "Return on Invested Capital (TTM)"

```
[13] "Gross Margin (TTM)"
[14] "Operating Margin (TTM)"
[15] "Net Margin (TTM)"
[16] "Price to Earnings Ratio (TTM)"
[17] "Price to Book (FY)"
[18] "Enterprise Value/EBITDA (TTM)"
[19] "EBITDA (TTM)"
[20] "EPS Diluted (TTM)"
[21] "EBITDA (TTM YoY Growth)"
[22] "EBITDA (Quarterly YoY Growth)"
[23] "EPS Diluted (TTM YoY Growth)"
[24] "EPS Diluted (Quarterly YoY Growth)"
[25] "Price to Free Cash Flow (TTM)"
[26] "Free Cash Flow (TTM YoY Growth)"
[27] "Free Cash Flow (Quarterly YoY Growth)"
[28] "Debt to Equity Ratio (MRQ)"
[29] "Current Ratio (MRQ)"
[30] "Quick Ratio (MRQ)"
[31] "Dividend Yield Forward"
[32] "Dividends per share (Annual YoY Growth)"
[33] "Price to Sales (FY)"
[34] "Revenue (TTM YoY Growth)"
[35] "Revenue (Quarterly YoY Growth)"
[36] "Technical Rating"
```

• The names of the data columns are self-explanatory. The Financial terms are explained in depth on multiple external websites such as www.Investopedia.com

#### 17.3.1 Rename Data Columns

4. The names of the data columns are lengthy and confusing. We will rename the data columns to make it easier to work with the data.

```
# Define a mapping of new column names
new_names <- c(
   "Date", "Stock", "StockName", "Sector", "Industry",
   "MarketCap", "Price", "Low52Wk", "High52Wk",
   "ROE", "ROA", "ROIC", "GrossMargin",
   "OperatingMargin", "NetMargin", "PE",
   "PB", "EVEBITDA", "EBITDA", "EPS",
   "EBITDA_YOY", "EBITDA_QYOY", "EPS_YOY",
   "EPS_QYOY", "PFCF", "FCF",</pre>
```

```
"FCF_QYOY", "DebtToEquity", "CurrentRatio",
"QuickRatio", "DividendYield",
"DividendsPerShare_YOY", "PS",
"Revenue_YOY", "Revenue_QYOY", "Rating"
)
# Rename the columns using the new_names vector
colnames(sp500)<-new_names
```

5. We review the column names again after renaming them, using the colnames() function can help.

colnames(sp500)

[1]	"Date"	"Stock"	"StockName"
[4]	"Sector"	"Industry"	"MarketCap"
[7]	"Price"	"Low52Wk"	"High52Wk"
[10]	"ROE"	"ROA"	"ROIC"
[13]	"GrossMargin"	"OperatingMargin"	"NetMargin"
[16]	"PE"	"PB"	"EVEBITDA"
[19]	"EBITDA"	"EPS"	"EBITDA_YOY"
[22]	"EBITDA_QYOY"	"EPS_YOY"	"EPS_QYOY"
[25]	"PFCF"	"FCF"	"FCF_QYOY"
[28]	"DebtToEquity"	"CurrentRatio"	"QuickRatio"
[31]	"DividendYield"	"DividendsPerShare_YOY"	"PS"
[34]	"Revenue_YOY"	"Revenue_QYOY"	"Rating"

#### 17.3.2 Understand the Data Columns

- 6. The complete data has 36 columns. Our next goal is to gain a deeper understanding of what the data columns mean. We reorganize the column names into eight tables, labeled Table 1a, 1b.. 1h.
- a. The column names described in Table 1a. concern basic **Company Information** of each stock.

	Table 1a: Data Columns giving basic Company Information
ColumnName	Description
Date	Date (e.g. "7/15/2023")
Stock	Stock Ticker (e.g. AAL)

Table 1a: Data Columns giving basic Company Information	
ColumnName	Description
StockName	Name of the company (e.g "American
	Airlines Group, Inc.")
Sector	Sector the stock belongs to (e.g.
	"Transportation")
Industry	Industry the stock belongs to (e.g "Airlines")
MarketCap	Market capitalization of the company
Price	Recent Stock Price

b. The column names described in Table 1b. are related to **Technical Analysis** of each stock, including the 52-Week High and Low prices.

Table 1b: Data Columns related to Pricing and Technical Analysis	
ColumnNam	e Description
Low52Wk	52-Week Low Price
${ m High52Wk}$	52-Week High Price
Rating	Technical Rating

c. The column names described in Table 1c. are related to the **Profitability** of each stock.

	Table 1c: Data Columns related to Profitability
ColumnName	Description
ROE	Return on Equity
ROA	Return on Assets
ROIC	Return on Invested Capital
GrossMargin	Gross Profit Margin
OperatingMargin	Operating Profit Margin
NetMargin	Net Profit Margin

d. The column names described in Table 1d are related to the **Earnings** of each stock.

	Table 1d: Data Columns related to Earnings
ColumnName	Description
PE	Price-to-Earnings Ratio
PB	Price-to-Book Ratio
EVEBITDA	Enterprise Value to EBITDA Ratio
EBITDA	EBITDA
EPS	Earnings per Share

Table 1d: Data Columns related to Earnings		
ColumnName	Description	
EBITDA_YOY	EBITDA Year-over-Year Growth	
EBITDA_QYOY	EBITDA Quarterly Year-over-Year Growth	
EPS_YOY	EPS Year-over-Year Growth	
$EPS_QYOY$	EPS Quarterly Year-over-Year Growth	

e. The column names described in Table 1e are related to the **Free Cash Flow** of each stock.

	Table 1e: Data Columns related to Free Cash Flow
ColumnName	Description
PFCF	Price-to-Free Cash Flow
FCF	Free Cash Flow
$FCF_QYOY$	Free Cash Flow Quarterly Year-over-Year
	Growth

f. The column names described in Table 1f concern the Liquidity of each stock.

Table 1f: Data Columns related to Liquidiy	
ColumnName	Description
DebtToEquity	Debt-to-Equity Ratio
CurrentRatio	Current Ratio
QuickRatio	Quick Ratio

g. The column names described in Table 1g are related to the **Revenue** of each stock.

	Table 1g: Data Columns related to Revenue
ColumnName	Description
PS	Price-to-Sales Ratio
Revenue_YOY	Revenue Year-over-Year Growth
Revenue_QYOY	Revenue Quarterly Year-over-Year Growth

h. The column names described in Table 1h are related to the **Dividends** of each stock.

	Table 1h: Data Columns related to Dividends
ColumnName	Description
DividendYield	Dividend Yield

Table 1h: Data Columns related to Dividends							
ColumnName	Description						
DividendsPerShare_YOY	Annual Dividends per Share Year-over-Year Growth						

# 17.3.3 Stock Ratings

1. In the data, the S&P500 shares have Technical Ratings such as {Strong Buy, Buy, Neutral, Sell, Strong Sell}. Since each Stock has a unique Technical Rating, it makes sense to model the data column Rating as a factor() variable.

```
sp500$Rating <- as.factor(sp500$Rating)</pre>
```

2. We confirm that Rating is now modelled as a factor variable, by running the str() function.

```
str(sp500$Rating)
```

```
Factor w/ 5 levels "Buy", "Neutral", ...: 3 3 5 5 3 3 3 2 5 5 ....
```

3. We can use the levels() function to review the different levels it can take.

```
levels(sp500$Rating)
```

- [1] "Buy" "Neutral" "Sell" "Strong Buy" "Strong Sell"
  - 4. The table() function allows us to count how many stocks have each Rating.

```
table(sp500$Rating)
```

Buy	Neutral	Sell	Strong Buy	Strong Sell
39	33	302	2	127

5. Thus, we can see how many stocks have ratings ranging from "Strong Sell" to "Strong Buy". This completes our review of Rating.

#### 17.3.4 Sectors within the S&P500

- The S&P 500 comprises a wide array of sectors, reflecting the diverse American corporate landscape.
- The data showcases the S&P500 divided across 19 Sectors. Here's an overview of the sectors, along with some representative companies:
- 1. Commercial Services (13 companies): This sector comprises firms offering services primarily to businesses. Example: Accenture, a management consulting and professional services firm.
- 2. Communications (3 companies): This sector covers companies involved in telecommunication and media. Example: AT&T, a telecommunications giant.
- 3. Consumer Durables (12 companies): Companies producing goods that aren't bought frequently and have a longer life, such as appliances and cars. Example: Whirlpool, an appliance manufacturer.
- 4. Consumer Non-Durables (32 companies): These are entities that produce goods that are consumed quickly or are non-reusable. Example: The Coca-Cola Company, known globally for its beverages.
- Consumer Services (29 companies): This includes companies that offer services directly to consumers. Example: Walt Disney Company, known for its entertainment services.
- 6. **Distribution Services (9 companies)**: Companies engaged in the distribution of products. Example: Sysco, a major food distributor.
- 7. Electronic Technology (49 companies): Represents companies engaged in electronics research and product development. Example: Apple, known for its iPhone and other electronic products.
- 8. **Energy Minerals (16 companies)**: Companies that extract and produce energy resources. Example: ExxonMobil, one of the world's largest oil and gas companies.
- Finance (92 companies): Covers banks, insurance companies, investment firms, RE-ITs and other financial institutions. Example: JPMorgan Chase, a leading global financial services firm.
- 10. **Health Services (12 companies)**: Includes providers of health services like hospital management. Example: HCA Healthcare, a major hospital operator.
- 11. **Health Technology (47 companies)**: Companies that produce medical equipment, pharmaceuticals, and other health-related tech. Example: Pfizer, a global pharmaceutical company.

- 12. **Industrial Services (9 companies)**: Firms providing services primarily to the industrial sector. Example: Caterpillar, a leading manufacturer of construction and mining equipment.
- 13. Non-Energy Minerals (7 companies): Companies involved in the extraction of minerals other than energy resources. Example: Vulcan Materials, a producer of construction aggregates.
- 14. **Process Industries (24 companies)**: This sector comprises entities that transform raw materials into finished goods. Example: Dow Inc., a major chemical manufacturer.
- 15. **Producer Manufacturing (31 companies)**: Companies engaged in the manufacturing of products for industries and consumers. Example: 3M, known for its diversified manufacturing.
- 16. **Retail Trade (22 companies)**: Companies directly involved in selling products to consumers. Example: Walmart, the multinational retail corporation.
- 17. **Technology Services (50 companies)**: Companies that offer tech services, including IT consulting and software services. Example: Microsoft, a global leader in software and cloud services.
- 18. **Transportation (15 companies)**: Covers companies involved in the transportation of goods and people. Example: Delta Air Lines, a major U.S. airline.
- 19. **Utilities (31 companies)**: Companies providing essential services like electricity, gas, and water. Example: Duke Energy, a prominent utility company.

## 17.3.5 Analysis of S&P 500 Sectors

1. The S&P500 shares are divided into multiple Sectors. Each stock belongs to a unique sector. Thus, it makes sense to model Sector as a factor() variable.

```
sp500$Sector <- as.factor(sp500$Sector)</pre>
```

2. We confirm that Sector is now modelled as a factor variable, by running the str() function.

```
str(sp500$Sector)
```

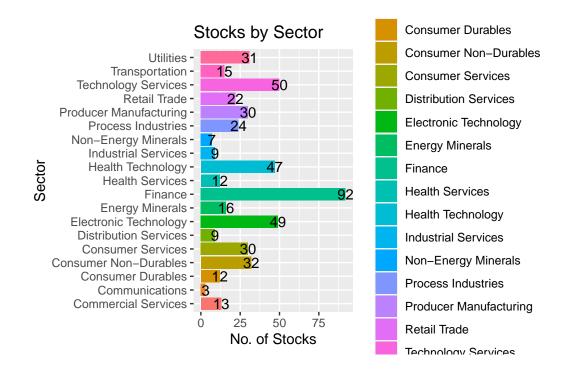

Factor w/ 19 levels "Commercial Services",..: 11 18 7 11 5 11 9 17 17 7 ...

3. We can use the levels() function to review the different levels it can take.

### levels(sp500\$Sector)

```
[1] "Commercial Services"
                               "Communications"
                                                         "Consumer Durables"
 [4] "Consumer Non-Durables"
                                                         "Distribution Services"
                               "Consumer Services"
                                                         "Finance"
 [7] "Electronic Technology"
                               "Energy Minerals"
[10] "Health Services"
                               "Health Technology"
                                                         "Industrial Services"
[13] "Non-Energy Minerals"
                               "Process Industries"
                                                         "Producer Manufacturing"
[16] "Retail Trade"
                               "Technology Services"
                                                         "Transportation"
[19] "Utilities"
```

• The S&P500 consists of 503 stocks, divided across 19 sectors.

• Thus, we can see how many stocks are part of each one of the 19 sectors. We can sum them to confirm that they add up to 503 stocks.

# 17.3.6 MarketCap by Sector

1. The S&P500 shares are divided into multiple Sectors. Each stock belongs to a unique sector. Thus, it makes sense to model Sector as a factor() variable.

We review the Market Cap of S&P500 stocks across Sectors.

```
MarketCapbySector <- sp500 %>%
  mutate(Market_Cap_Billions = round(MarketCap/1000000000, 2)) %>%
  group_by(Sector) %>%
  summarise(MarketCapBillions = sum(Market_Cap_Billions, na.rm = TRUE)) %>%
  arrange(-MarketCapBillions)

# Create a summary row
summary_row <- tibble(
  Sector = "Total",
  MarketCapBillions = sum(MarketCapbySector$Market_Cap_Billions)
)</pre>
```

Warning: Unknown or uninitialised column: `Market\_Cap\_Billions`.

```
# Append the summary row to the result
MarketCapbySector <- bind_rows(MarketCapbySector, summary_row)

# Render the table
MarketCapbySector %>%
   kable("html", caption = "Market Capitalization (Billions of USD) by S&P500 Sector") %>%
   kable_styling()
```

Table 17.10: Market Capitalization (Billions of USD) by S&P500 Sector

Sector	MarketCapBillions

# 17.4 Summary of Chapter - Exploring S&P500 Data

This chapter embarks on an exploration of the S&P500, a significant stock market index encompassing 500 major publicly traded companies in the U.S. The chapter introduces the index's role as a benchmark for assessing the overall health and performance of the U.S. stock market, maintained by S&P Dow Jones Indices.

This chapter skillfully guides readers through the intricacies of exploring S&P500 data, employing practical examples and R code to foster a deeper understanding of the dataset's structure and content. Further exploration is encouraged with a wealth of references for continued learning and analysis.

# 18 Live Case: S&P500 (REITs)

Sep 08, 2023

# 18.1 Objective

# 18.1.1 A1) Role Play?

Greetings Data Commandos!

Imagine you're in the bustling hub of the world's most elite consulting firms, revered across the corporate spectrum.

A prestigious investment fund is ready to channel \$1 Million into the US finance sector. They've enlisted your expertise to delve into the 29 REITs within the Finance sector of the S&P500.

Real Estate Investment Trusts, commonly known as REITs, offer a distinctive way to engage with real estate markets without the cumbersome process of directly owning property.

Your mission? Allocate \$1 Million to the "best" REIT(s). Pinpoint the top 1, 2 or 3 REITs that present the most promising short-term trading opportunities. Dive in and make those data-driven decisions!

# 18.1.2 A2) What are Prof. Sameer's learning objectives for you?

- 1. Revisit and solidify your knowledge of R programming, acquired or expected to be acquired in earlier courses.
- 2. Enhance your proficiency in data management and manipulation using the dplyr package and other functions in R.
- 3. Sharpen your skills in data visualization leveraging the ggplot2, ggpubr and related packages in R.
- 4. Master the art of addressing a data-centric business challenge while embodying the role of a Consulting Team.
- 5. Cultivate the capability to compellingly present your solutions to a discerning yet just audience.

# 18.2 Setup S&P 500 REIT Data

### 18.2.1 1. Load some useful R packages

```
# Load the required libraries, suppressing annoying startup messages
library(dplyr, quietly = TRUE, warn.conflicts = FALSE) # For data manipulation
library(tibble, quietly = TRUE, warn.conflicts = FALSE) # For data manipulation
library(ggplot2, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(ggpubr, quietly = TRUE, warn.conflicts = FALSE) # For data visualization
library(gsheet, quietly = TRUE, warn.conflicts = FALSE) # For Google Sheets
library(rmarkdown, quietly = TRUE, warn.conflicts = FALSE) # For writing
library(knitr, quietly = TRUE, warn.conflicts = FALSE) # For tables
library(kableExtra, quietly = TRUE, warn.conflicts = FALSE) # For tables
```

# 18.2.2 2. Read S&P500 data (to derive REIT data)

```
# Read S&P500 stock data present in a Google Sheet.
library(gsheet)
prefix <- "https://docs.google.com/spreadsheets/d/"
sheetID <- "11ahk9uWxBkDqrhNm7qYmiTwrlSC53N1zvXYfv7ttOCM"
url500 <- paste(prefix,sheetID) # Form the URL to connect to
sp500 <- gsheet2tbl(url500) # Read it into a tibble called sp500</pre>
```

#### 18.2.3 3. Rename Columns

```
# Define a mapping of new column names
new_names <- c(
   "Date", "Stock", "StockName", "Sector", "Industry",
   "MarketCap", "Price", "Low52Wk", "High52Wk",
   "ROE", "ROA", "ROIC", "GrossMargin",
   "OperatingMargin", "NetMargin", "PE",
   "PB", "EVEBITDA", "EBITDA", "EPS",
   "EBITDA_YOY", "EBITDA_QYOY", "EPS_YOY",
   "EPS_QYOY", "PFCF", "FCF",
   "FCF_QYOY", "DebtToEquity", "CurrentRatio",
   "QuickRatio", "DividendYield",</pre>
```

```
"DividendsPerShare_YOY", "PS",

"Revenue_YOY", "Revenue_QYOY", "Rating"
)

# Rename the columns using the new_names vector

colnames(sp500)<-new_names
```

#### 18.2.4 3. Select REIT data

- 1. The S&P500 shares are divided into multiple Sectors. Each stock belongs to a unique sector. Thus, it makes sense to model Sector as a factor() variable.
- 2. Set Sector, Rating data columns to be factor data types.

```
sp500$Sector <- as.factor(sp500$Sector)
sp500$Rating <- as.factor(sp500$Rating)</pre>
```

#### 18.2.5 C6. The Finance Sector within the S&P500

- 1. The Finance sector plays a pivotal role in the overall U.S. economy. Its performance is often closely watched by economists and investors alike, given its profound impact on lending, investment, and overall economic growth. Over the years, regulatory changes, monetary policy, and global economic events have significantly influenced this sector, making it a dynamic and critical component of the S&P 500.
- 2. We focus on investment opportunities within the Finance sector of the S&P500.
- We want to determine the fundamentally strongest AND most reasonably priced shares for short-to-medium term investing.
- 3. **Industry**: The Finance sector includes many industries within it.

### For example:

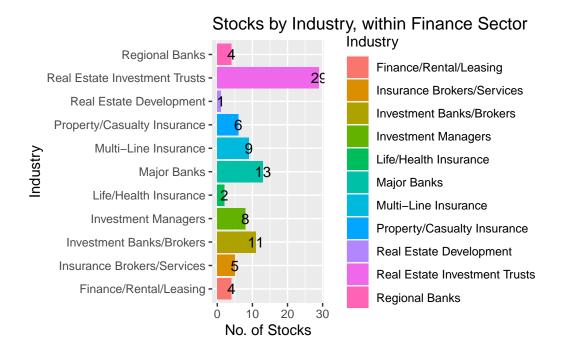

- Banks: JPMorgan Chase, Bank of America, and Wells Fargo, among others, represent the significant banking entities.
- Insurance Companies: Companies like Berkshire Hathaway, Allstate operate in this sub-sector, offering a range of insurance products from property and casualty insurance to life insurance.
- 4. We create a tibble named finStocks, filtering the shares that belong to the Finance sector.

```
finStocks = sp500 %>%
filter(Sector=="Finance")
```

- 5. Industries within the Finance Sector
- The data shows that the Finance sector consists of a total of 92 companies that belong to different Industries.
- We set the Industry to be factor variable, since they can only assume unique levels.

```
finStocks$Industry <- as.factor(finStocks$Industry)</pre>
```

• The following visualization summarizes the different Industries within the Finance Sector:

• Market Capitalization (Billions of USD) of Industries within the Finance Sector

```
FinanceMarketCap <- finStocks %>%
  mutate(MarketCap_Billions = round(MarketCap/1000000000, 2)) %>%
  group_by(Industry) %>%
  summarise(Market_Cap_BillionUSD = sum(MarketCap_Billions, na.rm = TRUE)) %>%
  arrange(-Market_Cap_BillionUSD)

# Create a summary row
summary_row <- tibble(
  Industry = "Total",
  Market_Cap_BillionUSD = sum(FinanceMarketCap$Market_Cap_BillionUSD)
)
# Append the summary row to the result
FinanceMarketCap <- bind_rows(FinanceMarketCap, summary_row)

# Render the table
FinanceMarketCap %>%
  kable("html", caption = "Market Capitalization (Billions of USD) of Finance Sector") %>%
  kable_styling()
```

Table 18.1: Market Capitalization (Billions of USD) of Finance Sector

Industry	Market_Cap_BillionUSD
Major Banks	1036.17
Property/Casualty Insurance	914.48
Real Estate Investment Trusts	833.22
Investment Banks/Brokers	594.79
Multi-Line Insurance	325.86
Investment Managers	313.20
Insurance Brokers/Services	248.11
Finance/Rental/Leasing	172.77
Regional Banks	140.10
Life/Health Insurance	43.41
Real Estate Development	22.27
Total	4644.38

• We focus on investment opportunities within a particular Industry – **Real Estate Investment Trusts**.

## 18.2.6 C7. Stock Prices, as of 10/8/2023

- 1. Stock Prices relative to their 52 Week Low and 52 Week High
- We want to analyze stock prices relative to their 52 Week Low and 52 Week High respectively, to understand their relative price attractiveness.
- For this purpose, we create some additional data columns.

```
finStocks = sp500 %>%
  filter(Sector=="Finance") %>%
  mutate(Low52WkPerc = round((Price - Low52Wk)*100 / Low52Wk,2)) %>%
  mutate(High52WkPerc = round((High52Wk - Price)*100 / Low52Wk,2)) %>%
  mutate(MarketCap_Billions = round(MarketCap/1000000000, 2))
```

Here, a new column named Low52WkPerc is being added. The column contains the
percentage change between the current price (Price) and its 52-week low (Low52Wk).
The formula used is:

$$Low52WkPerc = \frac{(CurrentPrice - 52WeekLow)*100}{52WeekLow}$$

- Another column named High52WkPerc represents the percentage change between the 52-week high (High52Wk) and the current price (Price).
- We round off the data to two decimal places for clarity.

```
finStocks$Price <- round(finStocks$Price,1)
finStocks$Low52Wk <- round(finStocks$Low52Wk,1)
finStocks$High52Wk <- round(finStocks$High52Wk,1)</pre>
```

# 18.3 D. REITs in the S&P500, as of 10/8/2023

- 1. Real Estate Investment Trusts, commonly known as REITs, stand as a cornerstone for investors seeking diversification in their portfolios. These entities offer a distinctive way to engage with real estate markets without the cumbersome process of directly owning property.
- 2. In our analysis of the Finance sector, we want to focus attention on a particular Industry within it **Real Estate Investment Trusts**.
- 3. Recall: We want to determine the fundamentally strongest AND most reasonably priced, top 1-3 REITs for short-to-medium term investing USD 1 Million.

## 18.3.1 D1. Key Characteristics of REITs:

- 1. **Income Distribution**: One of the most touted features of REITs is their consistent income flow. U.S. tax regulations mandate REITs to distribute at least 90% of their taxable income as dividends. While this can be enticing due to potentially higher yields, it also poses a risk. The high dividend mandate leaves REITs with less retained earnings, potentially hindering their growth or making them more dependent on external financing.
- 2. Liquidity versus Direct Ownership: REITs offer a stark contrast to traditional real estate investments in terms of liquidity. While selling a property might entail prolonged durations, hefty transaction costs, and price negotiations, REIT shares can be traded with the agility of stocks. This flexibility, however, comes at the cost of exposure to stock market volatility.
- 3. Tax Implications: The unique tax structure of REITs is a double-edged sword. While they can dodge corporate taxes by abiding by stringent regulations, such as the income distribution clause, shareholders often have to pay higher individual taxes on REIT dividends compared to qualified stock dividends.
- 4. **Sectoral Diversification**: REITs don't just represent traditional brick-and-mortar assets. From data centers to timberlands, they span diverse sectors, potentially providing portfolio diversification. However, the granularity in sectors necessitates that investors be judicious and knowledgeable about the specific type of real estate exposure they're obtaining.

#### 18.3.2 D2. Major U.S. REITs:

1. American Tower Corporation (AMT): Pioneering the realm of communication infrastructures, AMT emphasizes cell tower operations. While it highlights the evolution

- of REITs beyond traditional confines, it also underscores the need for REIT investors to comprehend tech industry dynamics, given its tech infrastructure focus.
- 2. **Prologis (PLD)**: With a niche in logistics and industrial real estate, Prologis stands out in the age of e-commerce. The company's assets, mainly distribution centers, are strategically situated in prime markets. However, the increasing demand for same-day deliveries and supply chain revamps could challenge Prologis' portfolio.
- 3. Simon Property Group (SPG): Catering predominantly to retail spaces, SPG faces the arduous task of reinventing malls in an era where brick-and-mortar stores battle online retailers. The company's resilience in nurturing mixed-use spaces might determine its long-term growth trajectory.
- 4. **Equity Residential (EQR)**: As urbanization continues, EQR's focus on high-density urban areas might seem lucrative. But, with telecommuting trends and urban exodus, it's pivotal to monitor how urban rental landscapes evolve.
- 5. **Digital Realty Trust (DLR)**: In the digital age, DLR taps into the data economy by majoring in data centers. While the tech boom supports such endeavors, DLR's growth could be contingent on global data regulations and tech infrastructure demands.

**References**: Please consider looking into the following well-known sources, which regularly publish information about REITs.

- National Association of Real Estate Investment Trusts (NAREIT) This organization is a representative voice for REITs in the U.S. They frequently release reports, articles, and data on the REIT industry.
- Major Financial News Outlets Outlets like The Wall Street Journal, Financial Times, and Bloomberg often feature articles on REITs, especially in their real estate or investment sections.
- The Journal of Real Estate Finance and Economics This academic journal covers a wide range of topics in real estate, including REITs.

#### 18.3.3 D3. REITs in the S&P500:

We create a tibble named REIT from within the Finance sector tibble finStocks. Specifically, we filter the shares that belong to the Real Estate Investment Trusts Industry, within the Finance sector.

```
REIT <- finStocks %>%
  filter(Industry == 'Real Estate Investment Trusts')
```

• The following table lists REITs within the Finance sector of the S&P500

```
REIT %>%
  select(Stock, StockName, Price, MarketCap_Billions) %>%
  arrange(desc(MarketCap_Billions)) %>%
  kable("html", caption = "REITs within Finance Sector of S&P500") %>%
  kable_styling()
```

Table 18.2: REITs within Finance Sector of S&P500

Stock	StockName	Price	MarketCap_Billions
PLD	Prologis, Inc.	108.2	103.70
AMT	American Tower Corporation (REIT)	159.5	75.38
EQIX	Equinix, Inc.	710.8	66.68
VTR	Ventas, Inc.	40.4	49.76
PSA	Public Storage	257.6	45.85
WELL	Welltower Inc.	80.2	42.40
CCI	Crown Castle Inc.	89.3	39.43
DLR	Digital Realty Trust, Inc.	116.2	35.79
O	Realty Income Corporation	48.6	34.72
SPG	Simon Property Group, Inc.	103.0	34.23
VICI	VICI Properties Inc.	28.2	29.03
EXR	Extra Space Storage Inc	118.2	25.20
AVB	AvalonBay Communities, Inc.	166.8	23.87
EQR	Equity Residential	57.5	21.93
WY	Weyerhaeuser Company	29.8	21.91
SBAC	SBA Communications Corporation	192.6	21.49
INVH	Invitation Homes Inc.	31.1	19.15
IRM	Iron Mountain Incorporated (Delaware)	57.8	17.12
ARE	Alexandria Real Estate Equities, Inc.	97.1	16.99
MAA	Mid-America Apartment Communities, Inc.	126.8	14.85
ESS	Essex Property Trust, Inc.	208.1	13.40
UDR	UDR, Inc.	35.0	11.58
HST	Host Hotels & Resorts, Inc.	15.5	11.33
REG	Regency Centers Corporation	57.1	10.79
KIM	Kimco Realty Corporation (HC)	16.7	10.60
CPT	Camden Property Trust	92.8	9.93
PEAK	Healthpeak Properties, Inc.	17.4	9.83
BXP	Boston Properties, Inc.	55.0	9.01
FRT	Federal Realty Investment Trust	87.2	7.27

- Consider the summary statistics of the Market Capitalization of the REITs within the  ${\rm S\&P500}$ 

```
REIT %>% summarise(
   N = n(),
   Mean = mean(MarketCap_Billions),
   SD = sd(MarketCap_Billions),
   Median = median(MarketCap_Billions),
   Q1 = quantile(MarketCap_Billions, 0.25),
   Q3 = quantile(MarketCap_Billions, 0.75),
   Min = min(MarketCap_Billions),
   Max = max(MarketCap_Billions),
   Sum = sum(MarketCap_Billions)
) %>%
   round(2) %>%
   kable("html", caption = "Summary Statistics of Market Capitalization of REITs (Billion Ukable_styling())
```

Table 18.3: Summary Statistics of Market Capitalization of REITs (Billion USD)

N	Mean	SD	Median	Q1	Q3	Min	Max	Sum
29	28.73	22.5	21.91	11.58	35.79	7.27	103.7	833.22

• As can be seen, the S&P500 consists of 29 REITs.

Recall.. A prestigious investment fund is ready to channel \$1 Million into the US finance sector. They've enlisted your expertise to delve into the 29 REITs within the Finance sector of the S&P500.

Recall Your mission? Pinpoint the top 1, 2 or 3 REITs that present the most promising short-term trading opportunities. How will you allocate your investment capital of USD 1 Million? Dive in and make those data-driven decisions!

• We want to determine the fundamentally strongest AND most reasonably priced shares for short-to-medium term investing.

Well done! Our data is now ready for analysis!!

7. Low52WkPerc: Create a new column MarketCapBillions = MarketCap/1000,000,000, as described in the chapter Live Case: S&P500 (1 of 3).

```
sp500 <- sp500 %>% mutate(MarketCapBillions = round(MarketCap/1000000000))
colnames(sp500)
```

```
[1] "Date"
                              "Stock"
                                                        "StockName"

# 18.5.5 Significance of 52-Week Low Price

The 52-week low price of a stock is a significant indicator for multiple reasons, especially when considering shares listed on major indices like the S&P 500. Here's why this metric is noteworthy:

- 1. **Historical Perspective**: The 52-week low offers a snapshot of how low the stock has traded over the past year relative to its current price, providing context about its price journey.
- 2. **Potential Entry Point**: Some investors view stocks that are near their 52-week low as potential buying opportunities, under the assumption that the stock might be undervalued and could rebound.
- 3. Psychological Level: Stocks approaching their 52-week low can be seen as testing a significant support level. If a stock consistently fails to breach its 52-week low, it might indicate that the market values the stock at that level, and it's resistant to falling below it.
- 4. Basis for Technical Analysis: For technical analysts or traders, the 52-week low serves as a critical reference point. A consistent breach of this level might signify a bearish trend, while a rebound can indicate potential recovery.
- 5. Yield Implications for Dividend Stocks: For dividend-paying stocks, a price near the 52-week low (assuming the dividend hasn't been cut) would imply a higher dividend yield, potentially making it attractive for income-seeking investors.
- Note of Caution: While the 52-week low is a valuable reference point, it's essential to interpret it in conjunction with other financial and market indicators. A stock trading near its 52-week low doesn't automatically make it a good buy, just as a stock trading near its 52-week high doesn't automatically make it overvalued. Comprehensive analysis, should inform investment decisions.
